1. INTRODUCTION

Let X be a smooth manifold of dimension $n + 1$ with boundary ∂X , equipped with an arbitrary smooth metric \bar{g} . A boundary-defining function on X is a function $x \geq 0$ such that $\partial X = \{x = 0\}$ and $dx \neq 0$ on ∂X . A *conformally compact* metric on the interior of X is a metric of the form

$$g = \frac{\bar{g}}{x^2}.$$

Such metrics were introduced by Mazzeo [10] as a generalization of the hyperbolic metric on \mathbb{B}^n . The metric g is necessarily complete. Any non-trapped geodesic γ approaches a point $y \in \partial X$, and as $t \rightarrow \infty$ all sectional curvatures at $\gamma(t)$ all approach the value $-\alpha(y)^2$, where

$$\alpha = |dx|_{\bar{g}} \text{ restricted to } \partial X.$$

Let $\alpha_0 = \inf_{\partial X} \alpha$ and $\alpha_1 = \sup_{\partial X} \alpha$.

Mazzeo established the basic properties of the spectrum of the p -form Laplacian associated to g and proved the appropriate Hodge theorem for this context. Here we will deal only with the Laplacian on functions, denoted simply by Δ since g is fixed throughout.

Date: October, 2000.

Supported in part by an NSF Postdoctoral Fellowship.

Theorem 1.1. [10, 11] *The essential spectrum of Δ is $[\frac{\alpha_0^2 n^2}{4}, \infty)$ and is absolutely continuous. There are no embedded eigenvalues except possibly at $\frac{\alpha_0^2 n^2}{4}$.*

The case where $\alpha = \alpha_0$ is constant is referred to as *asymptotically hyperbolic*, since sectional curvatures all approach $-\alpha_0^2$ at infinity. Note that constant curvature “at infinity” does not imply that g has constant curvature at any point.

For asymptotically hyperbolic metrics, Mazzeo-Melrose proved meromorphic continuation of the resolvent.

Theorem 1.2. [13] *If $\alpha = \alpha_0$ then the resolvent $R_\zeta = [\Delta - \alpha_0^2 \zeta(n - \zeta)]^{-1}$ has a meromorphic continuation to $\mathbb{C} \setminus \frac{1}{2}(n - \mathbb{N})$.*

The proof is by a parametrix construction which gives a detailed picture of the structure of the resolvent kernel. One sees, for example, that

$$R_\zeta : \dot{C}^\infty(X) \rightarrow x^\zeta C^\infty(X),$$

where $\dot{C}^\infty(X)$ is the space of smooth functions vanishing to infinite order at ∂X . This property leads to a “functional parametrization” of the continuous spectrum (see [16]). Given $f|_{\partial X} \in C^\infty(\partial X)$, we can solve away a Taylor series at the boundary to extend f smoothly into the interior in such a way that $[\Delta - \alpha_0^2 \zeta(n - \zeta)]x^{n-\zeta}f \in \dot{C}^\infty(X)$. Then by applying R_ζ to the remainder we construct a generalized eigenfunction u solving $[\Delta - \alpha_0^2 \zeta(n - \zeta)]u = 0$ with

$$(1.1) \quad u = x^{n-\zeta}f + x^\zeta f',$$

where $f' \in C^\infty(X)$. This u is uniquely determined by $f|_{\partial X}$, and the map $E_\zeta : f|_{\partial X} \mapsto u$ is called the Poisson operator, after the classical case. It defines a parametrization of the continuous spectrum by $C^\infty(\partial X)$. This construction also yields the scattering matrix $S_\zeta : f|_{\partial X} \mapsto f'|_{\partial X}$, which is a pseudodifferential operator of order $2\operatorname{Re} \zeta - n$. Note that as defined here, E_ζ and S_ζ depend on the choice of x . This dependence is easily removed by considering sections of a certain trivial line bundle instead of functions, but for our purposes it is much more convenient to fix a choice of x for the whole paper. The kernels of E_ζ and S_ζ can be derived from R_ζ and are meromorphic functions of $\zeta \in \mathbb{C} \setminus \frac{1}{2}(n - \mathbb{N})$.

This paper is devoted to the extension of such results to the general conformally compact case, with variable α . To heighten the analogy with the asymptotically hyperbolic case, we continue to use a spectral parameter ζ such that the relation to the eigenvalue λ is

$$\lambda = \alpha_0^2 \zeta(n - \zeta).$$

For constant α this association comes from the equation for indicial roots of $\Delta - \lambda$ (see §3). In the general case the indicial roots are variable, and even singular for certain values of λ . This complication is the source of interesting new features in the scattering theory.

To summarize the results of this paper:

1. The Mazzeo-Melrose parametrix construction can be used to obtain meromorphic continuation of the resolvent $[\Delta - \alpha_0^2 \zeta(n - \zeta)]^{-1}$ to the plane minus a set Γ which is a collection of intervals (Theorem 5.1). Figure 1 shows the region of meromorphic continuation, which is defined by the condition that the indicial root avoid the set $\frac{1}{2}(n - \mathbb{N}_0)$ and includes the portion of the continuous spectrum $\lambda \in (\frac{\alpha_0^2 n^2}{4}, \infty)$. Within the region of meromorphic continuation we can construct the Poisson kernel and scattering matrix as in the asymptotically hyperbolic case (Propositions 5.4 and 5.5).
2. We'll refer to the portion of the continuous spectrum inaccessible by meromorphic continuation, $\lambda \in [\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_1^2 n^2}{4}]$ as the *irregular* continuous spectrum. (This corresponds to the vertical solid line in Figure 1.) We analyze it through a limiting absorption principle. This means

FIGURE 1. The resolvent is meromorphic outside the marked intervals. The dotted line indicates the continuous spectrum, and \times 's represent possible poles.

FIGURE 2. Behavior of generalized eigenfunctions for the irregular continuous spectrum. Scattering occurs only where the curvature at infinity is $> -\frac{4\lambda}{n^2}$.

establishing the strong limit of $[\Delta - \alpha_0^2 \zeta(n - \zeta)]^{-1}$ as ζ approaches the line $\text{Re } \zeta = \frac{n}{2}$ from the right (Theorem 6.7). With this technique we show that the *scattering set*

$$W_\lambda = \{\alpha^2 < \frac{4\lambda}{n^2}\} \subset \partial X,$$

“parametrizes” the irregular continuous spectrum at λ . More precisely, for $f \in \dot{C}^\infty(W_\lambda)$ there is a unique solution of $[\Delta - \alpha_0^2 \zeta(n - \zeta)]u = 0$ having an asymptotic expansion with leading behavior

$$u \sim x^{n-\sigma(\zeta,y)} f(y) + x^{\sigma(\zeta,y)} f'(y) \text{ near } W_\lambda,$$

where σ is the (variable) indicial root defined in §3 and $f' \in C^\infty(W_\lambda)$ (Proposition 7.1). The restriction of u to a neighborhood intersecting the boundary only in $\{\alpha^2 > \frac{4\lambda}{n^2}\}$ is in L^2 . Thus, as illustrated in Figure 2, generalized eigenfunctions only “propagate out to infinity” on W_λ . By combining the local parametrix construction with the limiting absorption principle, we are able to construct the Poisson kernel, understand its structure near W_λ , and thus show that the scattering matrix is a pseudodifferential operator defined on W_λ (Theorem 7.2).

3. The edge of scattering set is the *crossover region* $\{\alpha^2 = \frac{4\lambda}{n^2}\} \subset \partial X$. If we assume that $\frac{2\sqrt{\lambda}}{n}$ is a regular value of α , so that the crossover region is a submanifold of ∂X , then we can undertake a direct construction of the resolvent $[\Delta - \alpha_0^2 \zeta(n - \zeta)]^{-1}$. The technique is to blow up the crossover region in X to resolve the singularities of the indicial root. Adapting the parametrix construction to this extra blow-up, we obtain a good parametrix from which the structure of the resolvent may be deduced. The result is a full picture of the boundary behavior of the resolvent kernel under this generic assumption on λ (Theorem 8.19).

This behavior of generalized eigenfunctions can be interpreted physically. Larger α corresponds to more rapid volume growth at infinity, so one would naturally expect waves traveling in such directions to diffuse more quickly. At low frequencies (relative to α) the diffusion effect is evidently strong enough to overcome propagation, while sufficiently high-frequency waves do propagate in all directions.

Scattering theory on hyperbolic manifolds has an extensive literature (see [5] for a review of the subject). For this case the absence of embedded eigenvalues was proven by Lax-Phillips in [8] and meromorphic continuation of the resolvent by Perry [17], independently of [13]. Perry also proved that the scattering operator was pseudodifferential and computed its symbol.

For asymptotically hyperbolic metrics, the parametrization of the spectrum as in (1.1), and the corresponding definition of the scattering matrix, again a pseudodifferential operator, was implicit in [13] (stated, for example, in [16]). The proof was given by Joshi-Sá Barreto [7], who prove an inverse result on the determination of asymptotics of the metric from the symbol of the scattering operator. The equivalence of resolvent and scattering resonances for asymptotically hyperbolic metrics was proven by Borthwick-Perry [1]. In [3] Guilloupé-Zworski establish an upper bound on the counting function for resonances, under the stronger assumption of hyperbolic ‘near infinity,’ i.e. outside a compact set. For the case of Einstein metrics which are asymptotically hyperbolic Lee proved that there is no discrete spectrum provided the Yamabe invariant of the induced conformal structure on ∂X is non-negative [9].

Outside of [10, 11] no work seems to have been done on conformally compact metrics in full generality. The phenomenon of a scattering operator defined for a frequency-dependent set of directions appears to be quite new, although the direction-dependence bears some analogy with recent results of Herbst-Skibsted on scattering by homogeneous potentials [4].

Acknowledgments. Thanks to Rafe Mazzeo for encouragement to undertake this project, and Richard Melrose for some very helpful suggestions. The work was stimulated by a workshop at the Stefan Banach International Mathematical Centre in Warsaw, August 1999, for which support is gratefully acknowledged.

2. BOUNDARY ASYMPTOTICS

Our main goal is to describe precisely the structure of the generalized functions, as well as the resolvent, Poisson, and scattering kernels. The first step is to introduce the spaces which will characterize the behavior of these functions at the boundary.

Let M be a smooth manifold with corners (see [14, 15] for basic definitions). The boundary hypersurfaces of M , themselves manifolds with corners, are labeled Y_j , $j = 1, \dots, p$, and we introduce corresponding boundary defining functions ρ_1, \dots, ρ_p . We are basically interested in functions which behave near Y_j like $\rho_j^{\beta_j}$ times a smooth function, for a set of index functions $\beta_j \in C^\infty(Y_j)$. However, to make a definition independent of the choice of ρ_j ’s, ‘smooth’ must be relaxed to ‘polyhomogeneous conormal’ with a particular index set. We’ll follow closely the definition of spaces of polyhomogeneous conormal functions in [14, 15], but give a self-contained presentation for the convenience of the reader.

The set of smooth vector fields tangent to the boundary is denoted by $\mathcal{V}_b(M)$. As an auxiliary space in the definition, define for a multi-index $m \in \mathbb{R}^p$ the space

$$\mathcal{A}^q(M) = \{u \in C^\infty(M^\circ) : (\mathcal{V}_b)^k u \in \rho^m L^\infty(M) \forall k\},$$

where M° denotes the interior and $\rho^m = \rho_1^{m_1} \dots \rho_p^{m_p}$. This is clearly invariant under the action of \mathcal{V}_b . Because of logarithmic terms it will be convenient to use the space

$$\mathcal{A}^{m-} = \bigcap_{m' < m} \mathcal{A}^{m'},$$

where $m' < m$ means $m'_j < m_j$ for each j .

Given ρ_j we choose a product decomposition $Y_j \times [0, \epsilon)_{\rho_j}$ of a neighborhood of Y_j in X . Within this product neighborhood the radial vector field is

$$V_j = \rho_j \partial_{\rho_j},$$

which we'll extend to the rest of M so as to define an element of $\mathcal{V}_b(M)$. V_j is determined independently of the product decomposition up to an element of $\rho_j \mathcal{V}_b(M)$.

Definition 2.1. For a family of smooth functions $\beta \in C^\infty(M; \mathbb{R}^p)$, the space $\mathcal{A}_\beta(M)$ of 'polyhomogeneous functions with variable order' consists of functions $u \in C^\infty(M^\circ)$ such that for any $m \in \mathbb{N}_0^p$ we have

$$\left[\prod_{l=1}^p \prod_{k=0}^{m_l-1} (V_j - k)^{k+1} \right] (\rho^{-\beta} u) \in \mathcal{A}^{m-}(M).$$

To signify vanishing to infinite order at a particular boundary face we'll use the notation $\beta_j = \infty$. The invariance of $\mathcal{A}_\beta(M)$ under the action of $\mathcal{V}_b(M)$ is immediate from the definition. When β is constant it is usual to define the spaces with operators $(V_j - \beta_j - k)$ acting on u . This is not equivalent here, unless each β_j is independent of ρ_j near $\rho_j = 0$. We will see below that one could always make this assumption, because $\mathcal{A}_\beta(M)$ depends only on $\beta_j|_{Y_j}$.

The space $\mathcal{A}_\beta(M)$ could just as well be characterized by the existence of asymptotic expansions. Near the boundary surface Y_j the expansion will take the form

$$(2.1) \quad u \sim \sum_{0 \leq l \leq k < \infty} \rho_j^{\beta_j + k} (\log \rho_j)^l a_{k,l},$$

for functions $a_{k,l}$ on Y_j . By this we mean that for any $q > 0$

$$(2.2) \quad \rho^{-\beta} u - \sum_{0 \leq l \leq k < q-1} \rho_j^k (\log \rho_j)^l \chi(\rho_j) a_{k,l} \in \mathcal{A}^{q(j)-}(M),$$

where $q(j)$ denotes the index set $(\dots, 0, q, 0, \dots)$ with q in the j -th place, and $\chi \in C^\infty([0, \infty))$ with $\chi = 1$ on $[0, \epsilon/2]$ and $\chi = 0$ on $[\epsilon, \infty)$, so that $\chi(\rho_j) a_{k,l}$ may be thought of as a function on M which vanishes outside the product neighborhood

To a multi-index β on M we can associate a multi-index $\beta^{(j)}$ on each face Y_j . If H_l is a boundary hypersurface of Y_j (and hence a corner of M), then set $\beta_l^{(j)} = \beta_k|_{H_l}$ where Y_k is the unique boundary surface such that H_l is a component of $Y_j \cap Y_k$.

Proposition 2.2. *If $u \in C^\infty(M^\circ)$, then $u \in \mathcal{A}_\beta(M)$ if and only if u has an asymptotic expansion at each boundary surface Y_j :*

$$u \sim \sum_{0 \leq l \leq k < \infty} \rho_j^{\beta_j + k} (\log \rho_j)^l a_{k,l},$$

where $a_{k,l} \in \mathcal{A}_{\beta^{(j)}}(Y_j)$

Proof. It suffices to prove the expansion for $\rho^{-\beta} u$, so we can assume $\beta = 0$. This is a special case of a result proven in [15] using the Mellin transform. We'll give a different proof using methods found in [6, 7].

It also suffices to consider a single face, say Y_1 . We'll work in a product neighborhood $Y_1 \times [0, 1)_t$ and ignore the cutoff χ in (2.2). From the definition we have

$$(2.3) \quad \left[\prod_{k=0}^q (t \partial_t - k)^{k+1} \right] u \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M).$$

Let

$$(2.4) \quad u_1 = \left[\prod_{k=1}^q (t\partial_t - k)^{k+1} \right] u,$$

so that (2.3) becomes the estimate

$$(2.5) \quad \partial_t(u_1) = f \in \mathcal{A}^{q(1)-}(M).$$

In particular, since $q > 0$ we see that u_1 approaches a limit as $t \rightarrow 0$, call it b_1 . This b_1 is a function on Y_1 , and since we also have estimates of the form

$$\partial_t(\mathcal{V}_b)^k u_1 \in \mathcal{A}^{q(1)-}(M),$$

we have uniform convergence of tangential derivatives $(\mathcal{V}_b)^k u_1$ as $t \rightarrow 0$, giving us bounds on $(\mathcal{V}_b)^k b_1$. This shows that $b_1 \in \mathcal{A}^0(Y_1)$. The same principle applies to the radial vector field estimates. For example, since

$$V_2 u_1 \in \mathcal{A}^{1(2)-}(M) \text{ and } \partial_t V_2 u_1 \in \mathcal{A}^{(q,1,0,\dots)-}(M)$$

the limit of $V_2 u_1$ exists as $t \rightarrow 0$ and equals $V_2|_{Y_1} b_1$. In this way we get an estimate $V_2|_{Y_1} b_1 < C(\rho_2|_{Y_1})^{1-\delta}$ for any $\delta > 0$. Repeating this argument with higher derivatives and at all boundary faces of Y_1 , we conclude that

$$b_1 \in \mathcal{A}_0(Y_1).$$

Integrating (2.5) from 0 to t gives

$$u_1 - b_1 = \int_0^t f \, dt.$$

Again using $q > 0$, it is easy to see that

$$\int_0^t f \, dt \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M),$$

and hence $u_1 - b_1 \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M)$. Setting $a_{0,0} = b_1 / \prod_{k=1}^q (-k)^{k+1}$, we thus derive from (2.4) that

$$(2.6) \quad \left[\prod_{k=1}^q (t\partial_t - k)^{k+1} \right] (u - a_{0,0}) \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M)$$

Now let

$$u_2 = \left[\prod_{k=2}^q (t\partial_t - k)^{k+1} \right] (u - a_{0,0}),$$

so that (2.6) implies

$$(t\partial_t - 1)^2 u_2 \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M).$$

This could be written

$$\partial_t[t^{-1}(t\partial_t - 1)u_2] \in \mathcal{A}^{(q-1)\langle 1 \rangle -}(M),$$

so assuming $q > 1$ we apply the above argument to find $b_2 \in \mathcal{A}^0(Y_1)$ such that

$$t^{-1}(t\partial_t - 1)u_2 - b_2 \in \mathcal{A}^{q(1)-}(M).$$

Rewrite this as

$$\partial_t[t^{-1}u_2 - (\log t)b_2] \in \mathcal{A}^{(q-1)\langle 1 \rangle -}(M).$$

Repeating the argument yet again, we find $b'_2 \in \mathcal{A}^0(Y_1)$ such that

$$u_2 - (t \log t)b_2 - tb'_2 \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M).$$

Then from b_2 and b'_2 we form $a_{1,1}$ and $a_{1,0}$ by linear combination so that

$$\left[\prod_{k=2}^q (t\partial_t - k)^{k+1} \right] \left(u - a_{0,0} - (t \log t) a_{1,1} - t a_{1,0} \right) \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M)$$

This procedure may be continued inductively up to $k = q - 1$, yielding

$$(2.7) \quad (t\partial_t - q)^{q+1} \left(u - \sum_{j=0}^{q-1} \sum_{l=0}^j t^j (\log t)^l a_{j,l} \right) \in \mathcal{A}^{(q+1)\langle 1 \rangle -}(M).$$

To remove the remaining derivatives, consider a function $F \in C^\infty(M^\circ)$ satisfying

$$(2.8) \quad (t\partial_t - q)F \in \mathcal{A}^{q\langle 1 \rangle -}(M),$$

which is equivalent to

$$\partial_t(t^{-q}F) = h \in \mathcal{A}^{(-1)\langle 1 \rangle -}(M).$$

Integrating from t to 1 gives

$$t^{-q}F = f(1) - \int_t^1 h \, dt.$$

Since we have $(\mathcal{V}_b)^k \int_t^1 h \, dt = O(\log t)$ by the estimates on h , we conclude that (2.8) implies $F \in \mathcal{A}^{q\langle 1 \rangle -}(M)$.

Applying this argument $(q + 1)$ times to (2.7) we obtain

$$u - \sum_{j=0}^{q-1} \sum_{l=0}^j t^j (\log t)^l a_{j,l} \in \mathcal{A}^{q\langle 1 \rangle -}(M),$$

where $a_{j,l} \in \mathcal{A}_0(Y_1)$. □

We will need a means to indicate subspaces of \mathcal{A}_β consisting of functions with truncated expansions, i.e. with a certain number of the leading coefficients set to zero. For $q \in \mathbb{N}^p$ define

$$(2.9) \quad \mathcal{A}_{\beta|q}(M) = \prod_{l=1}^p (\rho_l \ln \rho_l)^{q_l} \cdot \mathcal{A}_\beta(M).$$

A useful alternative characterization is

$$(2.10) \quad \mathcal{A}_{\beta|q}(M) = \rho^\beta \left[\prod_{l=1}^p \prod_{k=0}^{q_l-1} (V_j - k)^{k+1} \right] \rho^{-\beta} \cdot \mathcal{A}_\beta(M),$$

The proof of Proposition 2.2 shows that (2.9) and (2.10) are equivalent.

Generally one defines spaces of polyhomogeneous conormal functions with more general expansions, specifying explicitly the set of possible powers of ρ_j and $\log \rho_j$ at each face. One could do the same for variable orders, but the possible crossing of orders complicates the definition. Since we do not require such generality, in Definition 2.1 we have chosen to use the minimal set of powers consistent with variable order.

Lemma 2.3. *The space $\mathcal{A}_\beta(M)$ is independent of the choice of V_j and depends on β only through the restrictions $\beta_j|_{Y_j}$.*

Proof. Since V_j is unique up to $\rho_j \mathcal{V}_b(M)$, independence follows from the invariance of \mathcal{A}^q under \mathcal{V}_b .

To study the β dependence, for simplicity let us specialize to the case $p = 1$, i.e. a manifold with boundary X with boundary defining function x . It suffices to consider an index $\beta = xf$ where $f \in C^\infty(X)$, and show that $\mathcal{A}_0(X) \subset \mathcal{A}_{xf}(X)$. Define the commutator operators

$$Z_q = \left[\prod_{k=0}^{q-1} (x\partial_x - k)^{k+1}, x^{(xf)} \right].$$

By induction we will show that

$$(2.11) \quad Z_q : \mathcal{A}_0(X) \rightarrow \mathcal{A}_{0|q}(X).$$

Because $\mathcal{A}_{0|q}(X) \subset \mathcal{A}^{q-}(X)$, for $u \in \mathcal{A}_0(X)$ we can then estimate

$$\begin{aligned} \prod_{k=0}^{m-1} (x\partial_x - k)^{k+1} (x^{(xf)} u) &= Z_m u + x^{(xf)} \prod_{k=0}^{m-1} (x\partial_x - k)^{k+1} u \\ &\in \mathcal{A}^{m-}(X), \end{aligned}$$

and hence $u \in \mathcal{A}_{xf}$.

So the result follows once we establish (2.11). Z_1 is multiplicative,

$$Z_1 = x^{(xf)} [(x \log x + x)f + x^2 \log x (\partial_x f)],$$

and the mapping property $Z_1 : \mathcal{A}_0(X) \rightarrow \mathcal{A}_{0|1}(X)$ is immediate. For the inductive step, assume Z_q satisfies (2.11) and consider

$$Z_{q+1} u = (x\partial_x - q)^{q+1} Z_q u + [(x\partial_x - q)^{q+1}, x^{(xf)}] \prod_{k=0}^{q-1} (x\partial_x - k)^{k+1} u$$

By definition we have

$$(x\partial_x - q)^{q+1} : \mathcal{A}_{0|q}(X) \mapsto \mathcal{A}_{0|(q+1)}(X),$$

which takes care of the first term. And the second is a sum of terms of the form

$$(\mathcal{V}_b)^k \cdot Z_1 \cdot (\mathcal{V}_b)^{q-k} \prod_{k=0}^{q-1} (x\partial_x - k)^{k+1} u,$$

and so using (2.10) the desired mapping follows from $Z_1 : \mathcal{A}_{0|q}(X) \rightarrow \mathcal{A}_{0|(q+1)}(X)$.

The argument is the same in the general case, except that the induction must be done over \mathbb{N}^p . \square

3. INDICIAL ROOTS

It will be convenient to put the metric into a normal form. The proof of the following result may be adapted directly from [7], where $\alpha = 1$.

Proposition 3.1. *Let X be a compact manifold with g a conformally compact metric. There exists a product decomposition (x, y) near ∂X such that*

$$g = \frac{dx^2}{\alpha^2(y)x^2} + \frac{h(x, y, dy)}{x^2} + O(x^\infty).$$

Here $-\alpha(y)^2$ is the limiting curvature at infinity.

FIGURE 3. For fixed ζ , the indicial root σ varies with $y \in \partial X$.

For the rest of the paper we will assume that

$$(3.1) \quad g = \frac{dx^2}{\alpha^2(y)x^2} + \frac{h(x, y, dy)}{x^2},$$

in some product neighborhood of the boundary. The $O(x^\infty)$ correction is dropped for notational simplicity, since its effect on the various estimates and asymptotic expansions at the boundary would be trivial.

The corresponding Laplacian operator is

$$(3.2) \quad \Delta = \alpha^2 \left[-(x\partial_x)^2 + nx\partial_x - x^2(\partial_x \log \sqrt{h})\partial_x \right] + x^2\Delta_h - x^2(\partial_i \log \alpha)h^{ij}\partial_j.$$

The *indicial equation* in this context is obtained by setting the leading order term in $(\Delta - \lambda)x^\sigma$ equal to zero and solving for the indicial root σ as a function of λ . This yields

$$\alpha^2\sigma(n - \sigma) - \lambda = 0,$$

so σ depends on y through $\alpha(y)$.

In the hyperbolic case it is natural and customary to choose spectral parameter ζ equal to the indicial root. For variable α it seems natural to use the relation

$$(3.3) \quad \lambda = \alpha_0^2\zeta(n - \zeta),$$

so that at least the continuous spectrum still corresponds to the line $\text{Re } \zeta = \frac{n}{2}$. Then the indicial equation can be solved for $\sigma(\zeta, y)$

$$(3.4) \quad \sigma = \sigma(\zeta, y) = \frac{n}{2} + \sqrt{\frac{n^2}{4} - \frac{\alpha_0^2}{\alpha^2}\zeta(n - \zeta)}.$$

The square root has a natural interpretation such that $\text{Re } \sigma > n/2$ whenever $\text{Re } \zeta > n/2$, which breaks down only if $\frac{n^2}{4} - \frac{\alpha_0^2}{\alpha^2}\zeta(n - \zeta) = 0$ for some $y \in \partial X$. We can thereby define σ as an analytic function of ζ outside of the segment

$$\zeta \notin \left\{ \zeta = \frac{n}{2} + it : t^2 \leq \frac{n^2}{4} \left(\frac{\alpha_1^2}{\alpha_0^2} - 1 \right) \right\}.$$

The range of definition is extended to $\zeta \in \mathbb{C}$ by continuity, and Figure 3 shows the behavior of $\sigma(\zeta)$ as a function of y . The indicial root fails to be analytic at those values of ζ for which $\lambda \in [\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_1^2 n^2}{4}]$.

It turns out that meromorphic continuation of the resolvent requires not only that σ be an analytic function of ζ , but that σ avoid the points $\frac{1}{2}(n - \mathbb{N})$. Accordingly we define

$$\Gamma = \{ \zeta \in \mathbb{C} : \sigma(\zeta, y) \in \frac{1}{2}(n - \mathbb{N}_0) \text{ for some } y \in \partial X \},$$

as pictured in Figure 1. Since $\zeta \neq \frac{n}{2}$ implies $\sigma(\zeta, \cdot) \in C^\infty(\partial X)$, we may define $\mathcal{A}_\sigma(X)$ for $\zeta \in \mathbb{C} \setminus \Gamma$ by choosing an arbitrary smooth extension of $\sigma(\zeta, \cdot)$ off the boundary. (We will consider the case of singular σ starting in §6.)

Lemma 3.2. *Let $\zeta \in \mathbb{C} \setminus \Gamma$. Given $v \in \mathcal{A}_{\sigma|1}$, we can find $u \in \mathcal{A}_{\sigma|1}$ such that*

$$v - [\Delta - \alpha_0^2 \zeta(n - \zeta)]u \in \dot{C}^\infty(X).$$

Proof. The leading terms in the boundary expansion of v are

$$x^{\sigma+1}(\log x)g_1 + x^{\sigma+1}g_2,$$

where $g_1, g_2 \in C^\infty(X)$. Observe that for any $\psi \in C^\infty(X)$

$$[\Delta - \alpha_0^2 \zeta(n - \zeta)]x^{\sigma+1}(\log x)g_1 = \alpha^2(n - 2\sigma - 1)x^{\sigma+1}(\log x)g_1 + x^{\sigma+1}h_2 + R,$$

where $h_2 \in C^\infty(X)$ and $R \in \mathcal{A}_{\sigma|2}$. Provided that $\sigma \neq (n - 1)/2$ we can set

$$u_1 = \frac{1}{\alpha^2(n - 2\sigma - 1)} \left[x^{\sigma+1}(\log x)g_1 + x^{\sigma+1}(g_2 - h_2) \right],$$

so as to have

$$v - [\Delta - \alpha_0^2 \zeta(n - \zeta)]u_1 \in \mathcal{A}_{\sigma|2}$$

The remaining terms u_j are obtained by an obvious induction, with the requirement that $\sigma \notin \frac{1}{2}(n - \mathbb{N}_0)$ ensuring that no zeroes occur in denominators. Then using Borel's lemma we sum the series asymptotically at $x = 0$ to get $u \sim \sum u_j$. \square

Since σ is the indicial root, $[\Delta - \alpha_0^2 \zeta(n - \zeta)]x^\sigma f \in \mathcal{A}_{\sigma|1}$ for $f \in C^\infty(X)$, and we immediately conclude the following:

Corollary 3.3. *Let $\zeta \in \mathbb{C} \setminus \Gamma$. Given $f \in C^\infty(\partial X)$ we can solve*

$$[\Delta - \alpha_0^2 \zeta(n - \zeta)]u \in \dot{C}^\infty(X),$$

for $u \in \mathcal{A}_\sigma(X)$ such u has leading boundary term

$$u(x, y) \sim x^\sigma f(y) \text{ as } x \rightarrow 0.$$

4. PARAMETRIX CONSTRUCTION

The operator Δ is a member of a class of differential operators $\text{Diff}_0^m(X)$ (where m denotes the order) generated by $\mathcal{V}_0(X)$, the set of smooth vector fields on X which vanish at the boundary. In local coordinates \mathcal{V}_0 is generated by $x\partial_x$ and $x\partial_y$ (whereas \mathcal{V}_b is generated by $x\partial_x$ and ∂_y).

The *stretched product* $X \times_0 X$ was introduced in [13, 10] as the natural space on which to study integral kernels of operators in $\text{Diff}_0^m(X)$. To define it, let $S = \Delta(\partial X \times \partial X) \subset X \times X$, which is the intersection of the diagonal with the corner. The stretched product is formed by blowing up this submanifold, which is notated:

$$X \times_0 X = [X \times X; S].$$

As a set, $X \times_0 X$ is $X \times X$ with S replaced by a *front face* consisting of its (inward-pointing) spherical normal bundle, a procedure best thought of as the introduction of polar coordinates around S . The blow-up is illustrated in Figure 4. In local coordinates (x, y, x', y') for $X \times X$ corresponding to the product decomposition of X near ∂X the diagonal in the corner is $S = \{x = x' = y - y' = 0\}$.

Letting $r = \sqrt{x^2 + x'^2 + (y - y')^2}$, we introduce the coordinates $(\rho, \rho', \omega, r, y)$ for $X \times_0 X$, where

$$\rho = \frac{x}{r}, \quad \rho' = \frac{x'}{r}, \quad \omega = \frac{y - y'}{r}.$$

FIGURE 4. The diagonal S in the corner of $X \times X$ is blown up to form the stretched product $X \times_0 X$.

The boundary faces of $X \times_0 X$ are the front face $r = 0$, the *left face* $\rho = 0$, and the *right face* $\rho' = 0$. The blow-down map is denoted by

$$\beta : X \times_0 X \rightarrow X \times X.$$

The operators occurring in the parametrix construction are characterized by the behavior of the lifts of their distribution kernels to $X \times_0 X$. Since g is fixed, we can associate to each operator its distributional kernel with respect to the Riemannian density. (Using half-densities avoids this dependency and is thus better for many purposes, but it would introduce another layer of notation which we don't actually need at this point.)

The microlocalization of $\text{Diff}_0^m(X)$ is ${}^0\Psi^m(X)$, the space of pseudodifferential operators modeled on $\mathcal{V}_0(X)$. This was introduced in [13] and is often referred to as the ‘small calculus.’ An operator is in ${}^0\Psi^m(X)$ if the lift of its kernel to $X \times_0 X$ has conormal singularity of order m at the lifted diagonal which is extendible over the double across the front face. The lifted kernels are further required to vanish to infinite order at the left and right faces.

Let σ_l and σ_r be the pullbacks of σ through $\partial X \times X$ and $X \times \partial X$ and up to the left and right faces, respectively. We order the faces of $X \times_0 X$ left, right, and front. Under the assumption that σ is smooth we introduce the space ${}^0\Psi_{\sigma_l, \sigma_r}(X)$ of operators whose kernels satisfy

$$\beta^* K \in \mathcal{A}_{\sigma_l, \sigma_r, 0}(X \times_0 X),$$

but which furthermore are extendible across the front face (hence no logarithmic terms in the expansion there). The residual class in the construction is $\Psi_{\sigma_l, \sigma_r}(X)$, consisting of operators with kernels in $\mathcal{A}_{\sigma_l, \sigma_r}(X \times X)$.

For future reference, we record the following mapping properties.

Lemma 4.1.

$$\begin{aligned} {}^0\Psi^m(X) : \dot{C}^\infty(X) &\rightarrow \dot{C}^\infty(X) \\ {}^0\Psi_{\sigma_l, \sigma_r}(X) : \dot{C}^\infty(X) &\rightarrow \mathcal{A}_\sigma(X) \end{aligned}$$

Proof. The first property follows from a standard wave-front set argument. To prove the second, consider $A \in {}^0\Psi_{\sigma_l, \sigma_r}(X) : \dot{C}^\infty(X)$ and $f \in \dot{C}^\infty(X)$. We can compute Af by first pull f up to $X \times_0 X$ through the right, then multiplying by the lift of A times the Riemannian density (in the right factor), then pushing forward to X through the left. But the lift of f vanishes to infinite order

at both the right and front faces, and so the push-forward can in fact be written as an integral on $X \times X$:

$$Af(x, y) = \int F(x, y, x', y') dg(x', y'),$$

for some $F \in \mathcal{A}_{\sigma_l, \infty}(X \times X)$. Then $Af \in \mathcal{A}_\sigma(X)$ is established by moving derivatives under the integral. \square

As noted in [11], the Mazzeo-Melrose parametrix construction of [13] applies locally to the case of variable α without much alteration, provided we restrict to a neighborhood of the boundary where $\sigma \notin \frac{1}{2}(n - \mathbb{N}_0)$. The only real change in the construction is the addition of logarithmic terms. Lemma 3.2 shows that these are easily handled when solving away Taylor series at the boundary. In addition, we need to include logarithmic singularities in applications of the model hyperbolic resolvent on fibers of the front face, extending Proposition 6.19 of [13].

The model case in question is the hyperbolic Laplacian Δ_0 on \mathbb{B}^{n+1} , lifted to Q which is the blow-up of \mathbb{B}^{n+1} at a point on its boundary. On each fiber σ will be constant, so we can just work with the usual hyperbolic spectral parameter ζ . Let ρ, ρ' be defining functions for the two faces of Q , where $\rho = 0$ corresponds to the remnant of the original boundary (these would be the restrictions to the fiber of the coordinates introduced above). The space that we are concerned with is $\mathcal{A}_{\zeta, \zeta-l}(Q)$ (with logarithmic terms included even though ζ is constant). As in (2.9), an index $\zeta|k$ denotes a truncated expansion with leading term $\rho^{\zeta+k}(\log \rho)^k$.

Proposition 4.2. *For $k \in \mathbb{N}$, $l \in \mathbb{N}_0$, we can extend the model resolvent $R_0(\zeta) = [\Delta_0 + \zeta(n - \zeta)]^{-1}$ to a meromorphic map*

$$R_0(\zeta) : \mathcal{A}_{\zeta|k, \zeta-l}(Q) \rightarrow \mathcal{A}_{\zeta, \zeta-l}(Q),$$

with poles at $\zeta \in \frac{1}{2}(n - k - \mathbb{N}_0) \cup \frac{1}{2}(-l - \mathbb{N}_0)$ and also $-\mathbb{N}_0$ for n odd.

Proof. It is most convenient to argue in the model for Q given by the upper half-space blown up at the origin. Sticking to our convention that x is the boundary defining function, we use coordinates $(x, y) \in \mathbb{R}_+ \times \mathbb{R}^n$. The model Laplacian is

$$\Delta_0 = -(x\partial_x)^2 + nx\partial_x - (x\partial_y)^2.$$

With radial coordinate $r = \sqrt{x^2 + y^2}$, the defining functions for the faces of Q are $\rho = x/r$ and $\rho' = r$. According to Proposition 6.19 of [13], the model resolvent extends meromorphically to a map

$$(4.1) \quad R_0(\zeta) = [\Delta_0 - \zeta(n - \zeta)]^{-1} : \rho^{\zeta+k} \rho'^{\zeta-l} C^\infty(Q) \rightarrow \rho^\zeta \rho'^{\zeta-l} C^\infty(Q),$$

with poles as indicated above.

Let $f \in \mathcal{A}_{\zeta|k, \zeta-l}(Q)$. We'll solve the problem

$$(4.2) \quad (\Delta_0 - \zeta(n - \zeta))u = f,$$

in stages. First a simple computation shows that for $\psi \in \mathcal{A}_{0, \zeta-l}(Q)$,

$$\begin{aligned} & (\Delta_0 - \zeta(n - \zeta))\rho^{\zeta+k}(\log \rho)^m \psi \\ &= k(n - 2\sigma - k)\rho^{\zeta+k}(\log \rho)^m \psi \\ &+ (m - 1)\rho^{\zeta+k}(\log \rho)^{m-1} \psi_1 + (m - 1)(m - 2)\rho^{\zeta+k}(\log \rho)^{m-2} \psi_2 + v, \end{aligned}$$

where $\psi_1, \psi_2 \in \mathcal{A}_{0, \zeta-l}(Q)$ and $v \in \mathcal{A}_{\zeta|(k+1), \zeta-l}(Q)$. We can use this to solve away the asymptotic expansion in ρ , exactly as in Lemma 3.2, with poles at $\zeta \in \frac{1}{2}(n - k - \mathbb{N}_0)$. The result is $u_0 \in \mathcal{A}_{\zeta|k, \zeta-l}(Q)$ such that

$$(\Delta_0 - \zeta(n - \zeta))u_0 - f = f_1 \in \mathcal{A}_{\infty, \zeta-l}(Q).$$

Now suppose we want to solve

$$(4.3) \quad (\Delta_0 - \zeta(n - \zeta))w = (\log \rho')\psi,$$

where $\psi \in \rho^\infty \rho'^{\zeta-l} C^\infty(Q)$. By (4.1) we can apply R_0 to ψ . Then we have

$$(\Delta_0 - \zeta(n - \zeta))(\log \rho')R_0(\zeta)\psi = (\log \rho')\psi + [\Delta_0, \log \rho']R_0(\zeta)\psi.$$

A straightforward computation shows that

$$[\Delta_0, \log \rho'] \in \rho^2 \mathcal{V}_b(Q),$$

and $\rho^\infty \rho'^{\zeta-l} C^\infty(Q)$ is invariant under $\mathcal{V}_b(Q)$. Therefore

$$[\Delta_0, \log \rho']R_0(\zeta)\psi \in \rho^\infty \rho'^{\zeta-l} C^\infty(Q).$$

The model resolvent can be applied to this expression by (4.1). The solution to (4.3) is then

$$w = (\log \rho')R_0(\zeta)f - R_0(\zeta)[\Delta_0, \log \rho']R_0(\zeta)f,$$

with poles as indicated. By induction we can extend this trick to higher powers of $\log \rho'$.

By applying this argument to successive terms in the asymptotic expansion of f_1 in ρ' and asymptotically summing the resulting terms, we can find $u_1 \in \mathcal{A}_{\zeta, \zeta-l}(Q)$ such that

$$(\Delta_0 - \zeta(n - \zeta))u_1 - f_1 = f_2 \in \dot{C}^\infty(Q).$$

The solution to the original problem is now given by $u = u_0 - u_1 + R_0(\zeta)f_2$. \square

Using Lemma 3.2 and Proposition 4.2, the parametrix construction of [13] can be applied essentially verbatim to the case of variable α . Note that although a global result is stated in [13], the construction is entirely local.

Proposition 4.3. *For $\zeta \in \mathbb{C}/\Gamma$ there is a parametrix M_ζ , analytic in ζ , such that*

$$[\Delta - \alpha_0^2 \zeta(n - \zeta)]M_\zeta = I - F_\zeta$$

where $M_\zeta \in {}^0\Psi^{-2}(X) + {}^0\Psi_{\sigma_l, \sigma_r}(X)$ and the error term $F_\zeta \in \Psi_{\infty, \sigma_r}(X)$.

If $\zeta \in \Gamma$ we can construct a local parametrix with the same structure, defined in a neighborhood $G \times G \subset X \times X$ such that $\sigma(\zeta, y) \notin \frac{1}{2}(n - \mathbb{N}_0)$ on $G \cap \partial X$.

5. PARTIAL MEROMORPHIC CONTINUATION

Consider the parametrix M_ζ of Proposition 4.3 for $\zeta \in \mathbb{C} \setminus \Gamma$. As in the asymptotically hyperbolic case the error F_ζ is compact on weighted L^2 spaces so by the analytic Fredholm theorem there is a meromorphic inverse $(I - F_\zeta)^{-1}$. The resolvent is then given by $M_\zeta(I - F_\zeta)^{-1}$. Let $I + D_\zeta = (I - F_\zeta)^{-1}$. Then the relations

$$D_\zeta = F_\zeta + D_\zeta F_\zeta = F_\zeta + F_\zeta D_\zeta$$

can be used to show that $D_\zeta \in \Psi_{\infty, \sigma_r}(X)$ also. We then claim that $M_\zeta D_\zeta \in \Psi_{\sigma_l, \sigma_r}(X)$. Since this amounts to a special case of Lemma 8.16, we will not give a separate proof here. The result is:

Theorem 5.1. *As an operator $\dot{C}^\infty(X) \rightarrow C^\infty(X^\circ)$, the resolvent $R_\zeta = [\Delta - \alpha_0^2 \zeta(n - \zeta)]^{-1}$ has a meromorphic continuation to $\zeta \in \mathbb{C} \setminus \Gamma$. Moreover, the resolvent has the structure*

$$R_\zeta \in {}^0\Psi^{-2}(X) + {}^0\Psi_{\sigma_l, \sigma_r}(X) + \Psi_{\sigma_l, \sigma_r}(X).$$

As discussed in the introduction, in the asymptotically hyperbolic case the existence of a Poisson kernel and scattering matrix follows directly from this theorem [7]. We'll prove the corresponding implications of Theorem 5.1 in this section. The proofs are similar to those of [7], with some modifications necessitated by the variable orders.

As in the asymptotically hyperbolic case, the Poisson kernel will be obtained by restriction of the resolvent kernel. We continue to use the Riemannian density of g to identify operators with integral kernels. With this convention the Poisson kernel will be given up to a constant by

$$(5.1) \quad E_\zeta = x'^{-\sigma_r} R_\zeta|_{x'=0}.$$

E_ζ is most naturally described by its lift to

$$X \times_0 \partial X = [X \times \partial X; S],$$

where $S = \Delta(\partial X \times \partial X)$ as before. This $X \times_0 \partial X$ is naturally diffeomorphic to the right face of $X \times_0 X$ and has two boundary hypersurfaces, left and front.

Let $R_\zeta = A_\zeta + B_\zeta + C_\zeta$, decomposed as in Theorem 5.1. Since A_ζ is supported in a neighborhood of the lifted diagonal, we have

$$x'^{-\sigma_r} A_\zeta|_{x'=0} = 0.$$

Thus $E_\zeta = H_\zeta + Q_\zeta$, where

$$H_\zeta = x'^{-\sigma_r} B_\zeta|_{x'=0} \in \mathcal{A}_{\sigma_l, -\sigma_l}(X \times_0 \partial X),$$

and

$$Q_\zeta = x'^{-\sigma_r} C_\zeta|_{x'=0} \in \mathcal{A}_\sigma(X \times \partial X).$$

The characterization of H_ζ and Q_ζ as polyhomogeneous with variable order follows immediately from Proposition 2.2.

Let $h_0 = h(0, y, dy)$ be the metric on ∂X induced by \bar{g} . For $f \in \partial X$, define

$$(5.2) \quad E_\zeta f(x, y) = \int_{\partial X} E_\zeta(x, y, y') f(y') dh_0(y').$$

We will show that $E_\zeta f$ has an asymptotic expansion for $x = 0$ and compute the leading terms.

Lemma 5.2. *Let $u \in C^\infty(X^\circ)$ and $\alpha, \beta \in C^\infty(X)$ with $\alpha - \beta \notin \mathbb{Z}$. Suppose that for every $m > 0$ there exists $q \in \mathbb{N}$ such that*

$$\prod_{k=0}^q \left[x^\alpha (x\partial_x - k)^{k+1} x^{-\alpha} \right] \prod_{k=0}^q \left[x^\beta (x\partial_x - k)^{k+1} x^{-\beta} \right] u \in \mathcal{A}^{m-}(X).$$

Then

$$u \in \mathcal{A}_\alpha(X) + \mathcal{A}_\beta(X).$$

Proof. Let

$$(5.3) \quad u_p = \prod_{k=p+1}^q \left[x^\alpha (x\partial_x - k)^{k+1} x^{-\alpha} \right] \prod_{k=0}^q \left[x^\beta (x\partial_x - k)^{k+1} x^{-\beta} \right] u,$$

so that

$$\prod_{k=0}^p (x\partial_x - k)^{k+1} (x^{-\alpha} u_p) \in x^{-\alpha} \mathcal{A}^{m-}(X)$$

Assuming that $p < m - \text{Re } \alpha$, we can apply the argument from Lemma 2.2 to get $a_{j,l} \in C^\infty(X)$ such that

$$(5.4) \quad x^{-\alpha} u_p - \sum_{j=0}^{p-1} \sum_{l=0}^j x^j (\log x)^l a_{j,l} \in \mathcal{A}^{p-}(X).$$

Now If we define

$$(5.5) \quad w = \prod_{k=0}^q \left[x^\beta (x\partial_x - k)^{k+1} x^{-\beta} \right] u,$$

then from (5.3) the relation to u_p is

$$x^{-\alpha} u_p = \prod_{k=p+1}^q (x\partial_x - k)^{k+1} (x^{-\alpha} w).$$

By solving a linear system for the coefficients $b_{j,l}$ in terms of the $a_{j,l}$ we can rewrite (5.4) as

$$(5.6) \quad \prod_{k=p+1}^q (x\partial_x - k)^{k+1} \left(x^{-\alpha} w - \sum_{j=0}^{p-1} \sum_{l=0}^j x^j (\log x)^l b_{j,l} \right) \in \mathcal{A}^{p-}(X)$$

Suppose $F \in C^\infty(X^\circ)$ satisfies

$$(5.7) \quad (x\partial_x - k)F \in \mathcal{A}^{p-}(X),$$

for $k > p$. This implies

$$\partial_x(x^{-k}F) = h \in x^{-k-1}\mathcal{A}^{p-}(X).$$

Integrating from x to 1 gives

$$x^{-k}F = F(1) - \int_x^1 h \, dx.$$

We note that $(\mathcal{V}_b)^l \int_x^1 h \, dx = O(x^{p-k-\epsilon})$ for $\epsilon > 0$, so we conclude that (5.7) implies $F \in \mathcal{A}^{p-}(X)$. Applying this repeatedly to (5.6) gives

$$w - \sum_{j=0}^{p-1} \sum_{l=0}^j x^{\alpha+j} (\log x)^l b_{j,l} \in x^\alpha \mathcal{A}^{p-}(X).$$

Substituting back with the definition of w from (5.5) and once again solving a linear system for new coefficients, we get

$$(5.8) \quad \prod_{k=0}^q \left[x^\beta (x\partial_x - k)^{k+1} x^{-\beta} \right] \left(u - \sum_{j=0}^{p-1} \sum_{l=0}^j x^{\alpha+j} (\log x)^l c_{j,l} \right) \in x^\alpha \mathcal{A}^{p-}(X)$$

The matrix relating the $c_{j,l}$'s to the $b_{j,l}$'s is lower triangular, with diagonal entries of the form $(\alpha + j - \beta - k)$. Hence the requirement that $\alpha - \beta \notin \mathbb{Z}$ ensures the system is non-singular.

Now we let v be the function in parentheses in (5.8) and simply repeat the argument given above. Assuming $s < p + \operatorname{Re} \alpha - \operatorname{Re} \beta$, we obtain $d_{j,l} \in C^\infty(X)$ such that

$$u - \sum_{j=0}^{p-1} \sum_{l=0}^j x^{\alpha+j} (\log x)^l c_{j,l} - \sum_{j=0}^{s-1} \sum_{l=0}^j x^{\beta+j} (\log x)^l d_{j,l} \in x^\beta \mathcal{A}^{s-}(X).$$

This construction is possible for $s + \operatorname{Re} \beta < p + \operatorname{Re} \alpha < m$, and m can be arbitrarily large, so we have full asymptotic expansions. \square

Proposition 5.3. *For $f \in \dot{C}^\infty(W_\lambda)$ and $E_\zeta f$ defined by (5.2) we have*

$$E_\zeta f \in \mathcal{A}_\sigma(X) + \mathcal{A}_{n-\sigma}(X).$$

Proof. That $Q_\zeta f \in \mathcal{A}_\sigma(X)$ follows immediately from $Q_\zeta \in \mathcal{A}_\sigma(X \times \partial X)$, so we concentrate on H_ζ . The asymptotic properties of $E_\zeta f$ depend only on the behavior of $E_\zeta(x, y, y')$ near $x = 0$ and/or $y = y'$. So we can specialize to a particular coordinate neighborhood with coordinates $(x, y, z = y - y')$ and assume that all functions are compactly supported within this neighborhood. We can rewrite (5.2) as

$$E_\zeta f(x, y) = \int_{\mathbb{R}^n} w(x, y, y - z) dz,$$

for $w \in \mathcal{A}_{\sigma_l, -\sigma_l}(X \times_0 \partial X)$. On $X \times_0 \partial X$ we'll use coordinates $r = \sqrt{x^2 + z^2}$, $\rho = x/r$, $\omega = z/r$, and y . For convenience, we extend σ into the interior so as to be independent of x within the neighborhood of interest. So $\sigma_l = \sigma(y)$ does not depend on r , ρ , or ω .

Noting that

$$\int z \partial_z w dz = -n \int w dz$$

by integration by parts, we can move derivatives under the integral to get

$$(5.9) \quad (x \partial_x - \sigma)(x \partial_x - n + \sigma) E_\zeta f = \int (x \partial_x - \sigma_l)(x \partial_x + z \partial_z + \sigma_l) w dz$$

The lift of the vector fields appearing here to $X \times_0 \partial X$ is

$$\begin{aligned} x \partial_x &\longrightarrow \rho^2 r \partial_r + (1 - \rho^2) \rho \partial_\rho + \rho^2 \omega \partial_\omega \\ x \partial_x + z \partial_z &\longrightarrow r \partial_r \end{aligned}$$

Writing $w = \rho^{\sigma_l} r^{-\sigma_l} F$ for $F \in \mathcal{A}_{0,0}(X \times_0 \partial X)$, the integrand on the right in (5.9) becomes

$$(x \partial_x - \sigma_l)(r \partial_r + \sigma_l) w = \rho^{\sigma_l} r^{-\sigma_l} [\rho \partial_\rho + \rho^2(-2\sigma_l + r \partial_r - \rho \partial_\rho + \omega \partial_\omega)](r \partial_r) F$$

Now by the definition of the truncated spaces in §2),

$$\begin{aligned} (r \partial_r) F &\in \mathcal{A}_{0,0|1}(X \times_0 \partial X); \\ (\rho \partial_\rho)(r \partial_r) F &\in \mathcal{A}_{0|1,0|1}(X \times_0 \partial X). \end{aligned}$$

Also $r \partial_r - \rho \partial_\rho + \omega \partial_\omega \in \mathcal{V}_b(X \times_0 \partial X)$ and

$$\rho^2 \mathcal{A}_{0,0|1}(X \times_0 \partial X) \subset \mathcal{A}_{0|2,0|1}(X \times_0 \partial X),$$

so we conclude that

$$(x \partial_x - \sigma_l)(r \partial_r + \sigma_l) w \in \rho^{\sigma_l} r^{-\sigma_l} \mathcal{A}_{0|1,0|1} = \mathcal{A}_{\sigma_l|1,-\sigma_l|1}$$

Applying this argument inductively gives

$$(5.10) \quad \prod_{k=0}^{q-1} [(x \partial_x - \sigma - k)(x \partial_x - n + \sigma - k)]^{k+1} E_\zeta f = \int G dz,$$

where $G \in \mathcal{A}_{\sigma_l|q,-\sigma_l|q}$. For $q > m + \operatorname{Re} \sigma$ we have $\mathcal{A}_{\sigma_l|q,-\sigma_l|q} \subset \mathcal{A}^{(m,m)-}(X \times_0 \partial X)$. The lift of $\mathcal{V}_b(X)$ to $X \times_0 \partial X$ through the left lies in $r^{-1} \mathcal{V}_b(X \times_0 \partial X)$, so by passing derivatives under the integral and using the estimates on G we have

$$\int G dz \in \mathcal{A}^{(m-1)-}(X).$$

Hence for $q > m + \operatorname{Re} \sigma$ we obtain

$$\prod_{k=0}^{q-1} [(x \partial_x - \sigma - k)(x \partial_x - n + \sigma - k)]^{k+1} E_\zeta f \in \mathcal{A}^{(m-1)-}(X).$$

This has been derived under the assumption that σ is independent of x in the local neighborhood, so the result then follows from Lemma 5.2. \square

Proposition 5.3 shows that $E_\zeta f$ has two separate asymptotic expansions at $x = 0$. Let $x^\sigma a_0$ and $x^{n-\sigma} b_0$ be the leading terms for each. The coefficients a_0 and b_0 will be holomorphic functions of ζ for $\zeta \in \mathbb{C} \setminus \Gamma$, which is very useful for computing them. If ζ is such that $2 \operatorname{Re} \sigma - n > 0$, then

$$b_0(\zeta, y) = \lim_{x \rightarrow 0} x^{\sigma-n} \int_{\mathbb{R}^n} E_\zeta(x, y, y') \phi(y') dy',$$

where $\phi = f\sqrt{h_0}$. Introducing the coordinate $w = (y - y')/x$, we have

$$b_0(\zeta, y) = \lim_{x \rightarrow 0} \int_{\mathbb{R}^n} x^\sigma E_\zeta(x, y, y - xw) \phi(y - xw) dw.$$

Note that $x^\sigma E_\zeta \in \mathcal{A}_{2\sigma_l, 0}$. Write this as $\rho^\sigma F(r, \rho, \omega)$, where $F \in \mathcal{A}_{0,0}$. Noting that $r = x\sqrt{1 + |w|^2}$, $\rho = 1/\sqrt{1 + |w|^2}$ and $\omega = \rho w$, we have

$$b_0(\zeta, y) = \phi(y) \int_{\mathbb{R}^n} F(0, \rho, \rho w) \frac{dw}{(1 + |w|^2)^\sigma}.$$

Since F is bounded and $2 \operatorname{Re} \sigma > n$, the integral is convergent.

As pointed out in [7], $F(0, \rho, \rho w)$ can be computed from the restriction of R_ζ to the front face, i.e. the normal operator of R_ζ . Since this is just the model resolvent, we see that

$$(5.11) \quad b_0 = B(\sigma) f \sqrt{h_0},$$

where B is a universal meromorphic function depending on n but not on g . This formula is therefore valid for all $\zeta \in \mathbb{C} \setminus \Gamma$. Combining Proposition 5.3 with (5.11) gives us the following result: for $f \in C^\infty(\partial X)$ the function

$$u = \frac{1}{B(\sigma)\sqrt{h_0}} E_\zeta f$$

satisfies $[\Delta - \alpha_0^2 \zeta(n - \zeta)]u = 0$ and

$$u \sim x^{n-\sigma} f + x^\sigma f',$$

with $f' \in C^\infty(\partial X)$. We have thus proven:

Proposition 5.4. *With respect to the metric density of h_0 the Poisson kernel is*

$$\frac{1}{B(\sigma)\sqrt{h_0}} E_\zeta.$$

To understand how f' relates to f we must compute a_0 . If $2 \operatorname{Re} \sigma - n < 0$ then

$$a_0(\zeta, y) = \lim_{x \rightarrow 0} x^{-\sigma} \int_{\mathbb{R}^n} E_\zeta(x, y, y - z) \phi(y - z) dz.$$

Using the same definition of F as above,

$$x^{-\sigma} E_\zeta = r^{-2\sigma} F(r, \rho, \omega).$$

The limit can be taken directly

$$a_0(\zeta, y) = \int_{\mathbb{R}^n} |z|^{-2\sigma} F(|z|, 0, z/|z|) \phi(y - z) dz.$$

Hence the scattering matrix is given by

$$S_\zeta : f \mapsto \frac{1}{B(\sigma)\sqrt{h_0}} \int_{\mathbb{R}^n} \frac{F(|y - y'|, 0, \frac{y - y'}{|y - y'|})}{|y - y'|^{-2\sigma}} f(y') dh_0(y')$$

In computing the symbol of this pseudodifferential operator, the two factors of $\sqrt{h_0}$ cancel out (they would not have appeared if we worked with half-densities).

Proposition 5.5. *For $\zeta \in \mathbb{C} \setminus \Gamma$ the scattering matrix S_ζ is a meromorphic pseudodifferential operator on ∂X , with principal symbol*

$$2^{n-2\sigma} \frac{\Gamma(\frac{n}{2} - \sigma)}{\Gamma(\sigma - \frac{n}{2})} |\xi|_{h_0}^{2\sigma-n}.$$

6. LIMITING ABSORPTION

Let $R_\zeta = [\Delta - \alpha_0^2 \zeta(n - \zeta)]^{-1}$, as defined by the partial meromorphic continuation. Fix ζ with $\operatorname{Re} \zeta = n/2$ and $\operatorname{Im} \zeta \neq 0$, and choose a sequence $\zeta_j \rightarrow \zeta$ with $\operatorname{Re} \lambda_j > n/2$ and $\operatorname{Im} \zeta_j = \operatorname{Im} \zeta$. For fixed $f \in \dot{C}^\infty(X)$, the point of this section is to show that the sequence $R_{\zeta_j} f$ converges to the unique solution u of $[\Delta - \alpha_0^2 \zeta(n - \zeta)]u = f$ satisfying a certain ‘radiation’ condition. By this technique we are able to define R_ζ for ζ on the boundary of the region of analytic continuation, corresponding to the irregular continuous spectrum $\lambda \in (\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_0^2 n^2}{4}]$. We have to avoid $\lambda = \frac{\alpha_0^2 n^2}{4}$ because of the possible embedded eigenvalue there. However, if we had $\alpha = \alpha_0$ on some open set in ∂X then an embedded eigenvalue would be ruled out and the point $\zeta = \frac{n}{2}$ could be included as a possible limit point of $\{\zeta_j\}$.

The limiting absorption property relies on certain uniform estimates on $R_\zeta f$ for $\operatorname{Re} \zeta > \frac{n}{2}$. In the following, for complex valued 1-forms θ_1, θ_2 we’ll denote the metric inner product by

$$\langle \theta_1, \theta_2 \rangle = g^{-1}(\overline{\theta_1}, \theta_2).$$

For either functions or forms, (\cdot, \cdot) denotes the L^2 inner product, and $\|\cdot\|$ the L^2 norm.

To control the boundary terms in the propositions below, we first state a non-uniform result which is a simple consequence of Theorem 5.1 and Lemma 4.1.

Lemma 6.1. *For $\operatorname{Re} \zeta > n/2$, $f \in \dot{C}^\infty(X)$, there exists $\epsilon > 0$ (depending on ζ) such that*

$$R_\zeta f = O(x^{n/2+\epsilon}).$$

The first uniform estimate is relatively simple.

Proposition 6.2. *Let $u = R_\zeta f$ for $f \in \dot{C}^\infty(X)$ and $\operatorname{Re} \zeta > n/2$. For any $\delta > 0$*

$$\|x^\delta du\|^2 \leq C(|\lambda| \|x^\delta u\|^2 + \|f\|^2),$$

where $\lambda = \alpha_0^2 \zeta(n - \zeta)$ and C is independent of ζ .

Proof. Integrating by parts gives

$$\int_{x \geq s} x^{2\delta} \overline{u} \Delta u \, dg = \int_{x \geq s} \langle d(x^{2\delta} \overline{u}), du \rangle \, dg + \int_{x=s} x^{2\delta} \overline{u} (-\alpha x \partial_x u) \frac{dh}{x^n}$$

In taking the limit $s \rightarrow \infty$, the boundary term disappears by Lemma 6.1, yielding

$$(6.1) \quad \int x^{2\delta} \overline{u} \Delta u \, dg = \int \langle d(x^{2\delta} \overline{u}), du \rangle \, dg.$$

Using $(\Delta - \lambda)u = f$, we rewrite this as

$$\begin{aligned} \|x^\delta du\|^2 &= \int x^{2\delta} \overline{u} (\lambda u + f) \, dg - 2\delta \int x^{2\delta-1} \overline{u} \langle u \, dx, du \rangle \, dg \\ &= \lambda \|u\|^2 + (x^{2\delta} u, f) - 2\delta (x^{\delta-1} u \, dx, x^\delta du) \end{aligned}$$

Thus we can estimate

$$\|x^\delta du\|^2 \leq C(\|x^\delta u\|^2 + \|x^{2\delta} u\| \|f\| + \|x^\delta u\| \|x^\delta du\|).$$

We take care of the $\|x^\delta du\|$ on the right by an estimate of the form

$$\|x^\delta u\| \|x^\delta du\| \leq \epsilon \|x^\delta du\|^2 + \frac{1}{4\epsilon} \|x^\delta u\|,$$

and the result follows. \square

The second estimate establishes the radiation condition. It is also essentially just integration by parts, but a more complicated computation. The strategy is taken from a similar argument by Tayoshi [18], who established limiting absorption for a class of asymptotically flat metrics.

Fix $\zeta_0 \neq \frac{n}{2}$ with $\operatorname{Re} \zeta_0 = n/2$ and let $I_{\zeta_0} = \{\zeta_0 + t : 0 < t < 1\}$. For $\zeta \in I_{\zeta_0}$, the indicial root σ is smooth, but not uniformly so as $\zeta \rightarrow \zeta_0$. We thus need to be a little careful about the extension of σ into the interior. Away from the set $\{\alpha^2 = 4\lambda/n^2\}$ where $\sigma(\zeta_0)$ is singular any smooth extension will do. Near this set, however, we need to impose some uniformity. In such neighborhoods we will take

$$\tilde{\sigma}(\zeta, x, y) = \frac{n}{2} + \sqrt{\frac{n^2}{4} - \frac{\alpha_0^2}{\alpha^2} \zeta(n - \zeta) + ix}.$$

Such an extension has the following properties:

1. $\tilde{\sigma} \in C^0(X)$ is smooth in the interior and $\tilde{\sigma}|_{\partial X} = \sigma$.
2. The difference $\alpha^2 \tilde{\sigma}(n - \tilde{\sigma}) - \alpha_0^2 \zeta(n - \zeta)$ is $O(x)$, uniformly for $\zeta \in I_{\zeta_0}$.
3. $|d\tilde{\sigma}| = O(x^{1/2})$, uniformly for $\zeta \in I_{\zeta_0}$.

Proposition 6.3. *Fix $f \in \dot{C}^\infty(X)$ and extend σ into the interior as above. If $u = R_\zeta f$ for $\zeta \in I_{\zeta_0}$ then we can estimate*

$$\left\| x^{-\epsilon} \left(du - \tilde{\sigma}(\zeta) u \frac{dx}{x} \right) \right\|^2 < C(\|x^\delta u\|^2 + \|f\|^2),$$

where $\delta, \epsilon > 0$, $\delta + \epsilon < 1/2$, and C is independent of ζ .

Proof. Let us single out the operator appearing in the radiation condition by defining

$$d_{\tilde{\sigma}} u = du - \tilde{\sigma} u \frac{dx}{x}.$$

We first note that the only issue is to control $d_{\tilde{\sigma}} u$ at the boundary. Because for $t > 0$,

$$\int_{x \geq t} |d_{\tilde{\sigma}} u|^2 dg \leq C \int x^{2\delta} |d_{\tilde{\sigma}} u|^2 dg,$$

for any $\delta > 0$, and by Proposition 6.2, we have

$$\int x^{2\delta} |d_{\tilde{\sigma}} u|^2 dg \leq C(\|x^\delta u\|^2 + \|f\|^2)$$

So we will work in a product neighborhood of ∂X in which the metric has the form (3.1). Since $|\frac{dx}{\alpha x}| = 1$, the radial component of $d_{\tilde{\sigma}} u$ can be singled out as

$$D_{\tilde{\sigma}} u = \langle \frac{dx}{\alpha x}, d_{\tilde{\sigma}} u \rangle = \alpha(x \partial_x u - \tilde{\sigma} u).$$

We will also let $\gamma = x \partial_x \log \sqrt{h}$ so that

$$\operatorname{div}(\partial_x) = \frac{n+1-\gamma}{x}.$$

Let $s > 0$ be small enough that $[0, s] \times \partial X$ lies within the product neighborhood. For $\epsilon > 0$ we choose some $\psi \in C^\infty(0, \infty)$ such that

$$\psi(x) = \begin{cases} x^{-2\epsilon} & \text{if } x \leq s/2 \\ 0 & \text{if } x > s \end{cases}$$

We begin by computing a divergence:

$$(6.2) \quad \operatorname{div}[\alpha^{-1}\psi\overline{D_{\tilde{\sigma}}u}g^{-1}(d_{\tilde{\sigma}}u)] = \alpha^{-1}\psi\overline{D_{\tilde{\sigma}}u} \operatorname{div}g^{-1}(d_{\tilde{\sigma}}u) + \langle d(\alpha^{-1}\psi D_{\tilde{\sigma}}u), d_{\tilde{\sigma}}u \rangle$$

In the first term on the right-hand side we have

$$\begin{aligned} \operatorname{div}g^{-1}(d_{\tilde{\sigma}}u) &= -\Delta u + \operatorname{div}(\alpha^2\tilde{\sigma}ux\partial_x) \\ &= -\alpha_0^2\zeta(n-\zeta)u - f + \alpha^2\tilde{\sigma}x\partial_xu + \alpha^2\tilde{\sigma}(n-\gamma)u + \alpha^2(x\partial_x\tilde{\sigma})u \\ &= -f + \alpha\tilde{\sigma}D_{\tilde{\sigma}}u + Ru, \end{aligned}$$

where

$$R = \alpha_0^2\zeta(n-\zeta) - \alpha^2\tilde{\sigma}(n-\tilde{\sigma}) + \alpha^2(\tilde{\sigma}\gamma - x\partial_x\tilde{\sigma}).$$

Inserting back into (6.2), we have

$$\begin{aligned} (6.3) \quad \operatorname{div}[\alpha^{-1}\psi\overline{D_{\tilde{\sigma}}u}g^{-1}(d_{\tilde{\sigma}}u)] &= \langle d(\alpha^{-1}\psi D_{\tilde{\sigma}}u), d_{\tilde{\sigma}}u \rangle + \tilde{\sigma}\psi|D_{\tilde{\sigma}}u|^2 + \alpha^{-1}\psi\overline{D_{\tilde{\sigma}}u}(Ru - f) \\ &= \psi\langle d_{\tilde{\sigma}}(\alpha^{-1}D_{\tilde{\sigma}}u), d_{\tilde{\sigma}}u \rangle + x\psi'|D_{\tilde{\sigma}}u|^2 + \alpha^{-1}\psi\overline{D_{\tilde{\sigma}}u}(Ru - f) \end{aligned}$$

Now integrating the divergence on the left-hand side of (6.3) gives

$$\int \operatorname{div}[\alpha^{-1}\psi\overline{D_{\tilde{\sigma}}u}g^{-1}(d_{\tilde{\sigma}}u)]dg = \lim_{t \rightarrow 0^+} \int_{x=t} \alpha^{-1}\psi|D_{\tilde{\sigma}}u|^2 \frac{dh}{x^n},$$

and by Lemma 6.1 the boundary term is zero. Hence the integral of (6.3) gives

$$(6.4) \quad 0 = \int \left[\psi\langle d_{\tilde{\sigma}}(\alpha^{-1}D_{\tilde{\sigma}}u), d_{\tilde{\sigma}}u \rangle + x\psi'|D_{\tilde{\sigma}}u|^2 + \alpha^{-1}\psi\overline{D_{\tilde{\sigma}}u}(Ru - f) \right] dg$$

One more integration by parts is needed, to get rid of the second derivative of u appearing in the first term of the integrand in (6.4). To this end, note that

$$\begin{aligned} (6.5) \quad d_{\tilde{\sigma}}(\alpha^{-1}D_{\tilde{\sigma}}u) &= d_{\tilde{\sigma}}(x\partial_xu - \tilde{\sigma}u) \\ &= \mathcal{L}_{x\partial_x}(d_{\tilde{\sigma}}u) - u d\tilde{\sigma} - \tilde{\sigma}d_{\tilde{\sigma}}u. \end{aligned}$$

On substituting this into (6.4), the second derivative of u would be contained in the term

$$\int \psi\langle \mathcal{L}_{x\partial_x}d_{\tilde{\sigma}}u, d_{\tilde{\sigma}}u \rangle$$

This can be integrated by parts to give

$$-\frac{1}{2} \int \left[(x\psi' + (\gamma - n)\psi)|d_{\tilde{\sigma}}u|^2 + \psi(\mathcal{L}_{x\partial_x}g^{-1})(\overline{d_{\tilde{\sigma}}u}, d_{\tilde{\sigma}}u) \right] dg,$$

with a boundary term of

$$\lim_{t \rightarrow 0^+} \frac{1}{2} \int_{x=t} \alpha^{-1}\psi|d_{\tilde{\sigma}}u|^2 \frac{dh}{x^n} = 0$$

(again by Lemma 6.1). Combining this integration by parts with (6.5) and substituting back into (6.4) we now have

$$\begin{aligned} (6.6) \quad 0 &= \int \left[-\frac{1}{2}(x\psi' + (\gamma - n)\psi)|d_{\tilde{\sigma}}u|^2 - \frac{1}{2}\psi(\mathcal{L}_{x\partial_x}g^{-1})(\overline{d_{\tilde{\sigma}}u}, d_{\tilde{\sigma}}u) \right. \\ &\quad \left. - \psi\langle u d\tilde{\sigma}, d_{\tilde{\sigma}}u \rangle - \psi\tilde{\sigma}|d_{\tilde{\sigma}}u|^2 + x\psi'|D_{\tilde{\sigma}}u|^2 + \alpha^{-1}\overline{D_{\tilde{\sigma}}u}(Ru + f) \right] dg \end{aligned}$$

The Lie derivative of g^{-1} may be expressed in terms of h^{-1} :

$$-\frac{1}{2}\mathcal{L}_{x\partial_x}g^{-1} = x^2h^{-1} + \frac{1}{2}x^3\partial_xh^{-1}$$

Since $g^{-1} = \alpha^2 x^2 \partial_x \otimes \partial_x + x^2 h^{-1}$, for some $k < 1$ fixed we will have

$$(6.7) \quad -\frac{1}{2} \mathcal{L}_{x\partial_x} g^{-1} - k[g^{-1} - \alpha^2 x^2 \partial_x \otimes \partial_x] \geq 0,$$

as a tensor, for x sufficiently small. Recalling that ψ was to be supported in $[0, s]$, we require that s be sufficiently small so that (6.7) holds for $x < s$. Applying (6.7) to the relevant term in (6.6) gives

$$-\frac{1}{2} \psi (\mathcal{L}_{x\partial_x} g^{-1}) (\overline{d_{\tilde{\sigma}} u}, d_{\tilde{\sigma}} u) \geq k \psi (|d_{\tilde{\sigma}} u|^2 - |D_{\tilde{\sigma}} u|^2)$$

Using this in (6.6) along with the fact that $\operatorname{Re} \tilde{\sigma} > \frac{n}{2}$, we obtain an inequality

$$(6.8) \quad \begin{aligned} & \int \left[\left(\frac{1}{2} x \psi' + \frac{1}{2} \psi \gamma + k \psi \right) |d_{\tilde{\sigma}} u|^2 - (x \psi' + k \psi) |D_{\tilde{\sigma}} u|^2 \right] dg \\ & \leq \int \operatorname{Re} \left[-\psi \langle u, d_{\tilde{\sigma}} \rangle + \psi \overline{D_{\tilde{\sigma}} u} (Ru + \alpha^{-1} f) \right] dg \end{aligned}$$

Recalling that $\psi = x^{-2\epsilon}$ for $x < s/2$, we split the integral on the left-hand side of (6.8) to yield

$$(6.9) \quad \begin{aligned} & \int_0^{s/2} x^{-2\epsilon} \left[(-\epsilon + \frac{1}{2} \gamma + k) |d_{\tilde{\sigma}} u|^2 - (k - 2\epsilon) |D_{\tilde{\sigma}} u|^2 \right] dg \\ & \leq \int x^{-2\epsilon} \operatorname{Re} \left[-\langle u, d_{\tilde{\sigma}} \rangle + \overline{D_{\tilde{\sigma}} u} (Ru + \alpha^{-1} f) \right] dg + C \int_{s/2}^{\infty} |d_{\tilde{\sigma}} u|^2 dg \end{aligned}$$

We can pick $\epsilon < k/2$, and since $\gamma = O(x)$, by choosing s sufficiently small we can assume $\epsilon + \gamma/2 > c > 0$. Noting also that $|D_{\tilde{\sigma}} u| \leq |d_{\tilde{\sigma}} u|$, the left-hand side can be bounded below by

$$c \int_0^{s/2} x^{-2\epsilon} |d_{\tilde{\sigma}} u|^2 dg.$$

Applying this bound together with the estimates

$$|d_{\tilde{\sigma}}| = O(x^{1/2}), \quad R = O(x^{1/2}),$$

we derive from (6.9) the new inequality

$$(6.10) \quad \begin{aligned} & \int_0^{s/2} x^{-2\epsilon} |d_{\tilde{\sigma}} u|^2 dg \leq C \int \left[x^{1/2-2\epsilon} |u| |d_{\tilde{\sigma}} u| + x^{1/2-2\epsilon} |D_{\tilde{\sigma}} u| |u| \right. \\ & \quad \left. + x^{-2\epsilon} |D_{\tilde{\sigma}} u| |f| \right] dg + C \int_{s/2}^{\infty} |d_{\tilde{\sigma}} u|^2 dg. \end{aligned}$$

By Proposition 6.2 the L^2 norm of $x^{1+\delta} \partial_y u$ is bounded by that of $x^\delta u$ for $\delta > 0$. And $\int_{s/2}^{\infty} |d_{\tilde{\sigma}} u|^2 dg$ is estimated as indicated at the start of the proof. With these facts we can reduce (6.10) to

$$\|x^{-\epsilon} d_{\tilde{\sigma}} u\|^2 \leq C \left(\|x^\delta u\|^2 + \|x^{1/2-\epsilon} u\| \|x^{-\epsilon} D_{\tilde{\sigma}} u\| + \|f\| \|x^{-\epsilon} D_{\tilde{\sigma}} u\| \right).$$

Since $|D_{\tilde{\sigma}} u| \leq |d_{\tilde{\sigma}} u|$, if we set $\delta < 1/2 - \epsilon$ this yields the stated inequality. \square

The final step in establishing limiting absorption is a uniqueness result needed to guarantee that the sequence $R_{\zeta_j} f$ converges.

Proposition 6.4. *Fix $\lambda > \frac{n^2 \alpha^2}{4}$ and let $G \subset X$ be some neighborhood intersecting ∂X in W_λ . Suppose on G there exists a solution u to*

$$[\Delta - \lambda]u = 0, \quad u \in x^{-\delta} L^2(G)$$

for $\delta > 0$, satisfying the radiation condition:

$$d_{\tilde{\sigma}} u \in x^\gamma L^2(G; T^* X),$$

for $\gamma > 0$. Then $u = 0$.

Proof. Mazzeo argued in [11] that the existence of a local parametrix in $G \times G$ as in Proposition 4.3 shows that there can be no solution of $[\Delta - \lambda]u = 0$ lying in $L^2(G)$. So the point here is to use the radiation condition to argue that u would have to be L^2 .

Let χ be a cutoff in $C_0^\infty(G \cap \partial X)$. Choose $\psi \in C^\infty(\mathbb{R}_+)$ with $\psi = 0$ for $x \leq 1/4$, $\psi = 1$ for $x \geq 2$, and $\psi' \geq 1$ for $1/2 \leq x \leq 1$. Setting $\psi_\epsilon(x) = \psi(x/\epsilon)$, we can interpret $\psi_\epsilon \chi$ as a function on X using the product neighborhood on which the metric has the normal form (3.1). Assume ϵ is small enough that $\psi_\epsilon \chi$ is supported in G .

Assuming that u is as stated, we have

$$(6.11) \quad (u, [\Delta, \psi_\epsilon \chi]u) = (\bar{\lambda} - \lambda)(u, \psi_\epsilon \chi u) = 0$$

Choose ϵ small enough that $[\Delta, \psi_\epsilon \chi]u = 0$ for $x \geq 1$. Then (6.11) becomes

$$(6.12) \quad \int_0^1 \bar{u} [\Delta, \psi_\epsilon \chi]u \, dg = 0.$$

The commutator is

$$[\Delta, \psi_\epsilon \chi]u = (\chi \Delta \psi_\epsilon + \psi_\epsilon \Delta \chi) - 2\chi(x\partial_x \psi_\epsilon)(x\partial_x u) - 2\psi_\epsilon x^2 h^{ij}(\partial_j \chi)(\partial_j u)$$

Substituting this back into (6.12) and taking the imaginary part yields

$$(6.13) \quad 2 \operatorname{Im} \int_0^1 \chi \bar{u} (x\partial_x \psi_\epsilon)(x\partial_x u) \, dg = -2 \operatorname{Im} \int_0^1 \bar{u} \psi_\epsilon x^2 h^{ij}(\partial_j \chi)(\partial_j u) \, dg$$

Let $v = (x\partial_x - \sigma)u$, which lies in $x^\gamma L^2(G)$ by assumption. Then we can write (6.13) as

$$(6.14) \quad \int_0^1 \chi |u|^2 (\operatorname{Im} \sigma)(x\partial_x \psi_\epsilon) \, dg = - \operatorname{Im} \int_0^1 \bar{u} [\psi_\epsilon x^2 h^{ij}(\partial_j \chi)(\partial_j u) + \chi(x\partial_x \psi_\epsilon)v] \, dg$$

The first term on the right can be bounded:

$$\left| \int_0^1 \bar{u} [\psi_\epsilon x^2 h^{ij}(\partial_j \chi)(\partial_j u)] \, dg \right| \leq C \int_{\epsilon/4}^{2\epsilon} x |u| |d_y u| \, dg$$

By assumption $u \in x^{-\delta} L^2$ and $d_y u \in x^\gamma L^2$, so $|u| |d_y u|$ is integrable with respect to dg . Thus this first term can be estimated $O(\epsilon)$. For the second term on the right-hand side of (6.14) we have the bound

$$\left| \int_0^1 \chi(x\partial_x \psi_\epsilon) \bar{u} v \, dg \right| \leq C \int_{\epsilon/4}^{2\epsilon} \frac{x}{\epsilon} |u| |v| \, dg.$$

Since $x^{-\gamma+\delta} |u| |v|$ is integrable, this term can be estimated $O(\epsilon^\gamma)$ for small $\gamma > 0$.

Since $\operatorname{Im} \sigma$ is bounded from below in the support of χ , using these estimates back in (6.14) gives

$$\int_0^1 \chi |u|^2 (x\partial_x \psi_\epsilon) \, dg = O(\epsilon^\gamma).$$

In fact, since $\psi' \geq 1$ on the interval $[\frac{1}{2}, 1]$

$$\int_{\epsilon/2}^\epsilon \chi |u|^2 \, dg = O(\epsilon^\gamma).$$

We conclude that $\int_0^1 \chi |u|^2 \, dg$ is finite. By Mazzeo's uniqueness result, $u = 0$. □

We now have all the tools in place for limiting absorption.

Proposition 6.5. *Fix ζ with $\operatorname{Re} \zeta = n/2$ and choose a sequence $\zeta_j \rightarrow \zeta$ with $\operatorname{Im} \zeta_j = \operatorname{Im} \zeta$ and $\operatorname{Re} \zeta_j > n/2$. As $\zeta_j \rightarrow \zeta$, $R_{\zeta_j} f$ converges in $x^{-\delta} L^2(X)$ to the unique solution of*

$$[\Delta - \alpha_0^2 \zeta(n - \zeta)]u = f$$

for which $d_{\bar{\sigma}} u \in x^\epsilon L^2(X; T^*X)$.

Proof. Let $u_j = R_{\zeta_j} f$. Suppose that $\|x^\delta u_j\| \rightarrow \infty$. Then we can define a new sequence $v_j = u_j / \|x^\delta u_j\|$ so that $\|x^\delta v_j\| = 1$ and

$$(\Delta - \alpha_0^2 \zeta_j(n - \zeta_j))v_j = \frac{f}{\|x^\delta u_j\|} \rightarrow 0$$

By Proposition 6.2, v_j is a bounded sequence in $x^{-\delta} H_0^1$. Since the inclusion $x^{-\delta} H_0^1 \subset x^{-\delta} L^2$ is compact, any subsequence of v_j has a subsequence converging in $x^{-\delta} L^2$. The limit v of and such subsequence satisfies $[\Delta - \alpha_0^2 \zeta(n - \zeta)]v = 0$ and by Proposition 6.3 it also satisfies $x^{-\epsilon} \chi d_{\bar{\sigma}} v \in L^2$. Thus by Proposition 6.4 $v = 0$. Since $\|x^\delta v_j\| = 1$ this is not possible.

The conclusion is that u_j is a bounded sequence in $x^{-\delta} L^2$. By the same reasoning we applied to v_j above, any subsequence of u_j has a subsequence converging in $x^{-\delta} L^2$ to some u such that $[\Delta - \alpha_0^2 \zeta(n - \zeta)]u = f$ and $x^{-\epsilon} \chi d_{\bar{\sigma}} u \in L^2$. Since such a u is unique by Proposition 6.4 and therefore independent of the subsequence, we have $u_j \rightarrow u$. \square

Using the local parametrix we can refine the estimates on u considerably. In order to avoid the singularities of σ we introduce:

$$(6.15) \quad \begin{aligned} \chi \in C^\infty(X) : \quad & \chi = 0 \text{ on a neighborhood of } \{\alpha^2 = \frac{4\lambda}{n^2}\}, \\ \sigma_{reg} \in C^\infty(\partial X) : \quad & \sigma_{reg} = \sigma \text{ on } \operatorname{supp}(\chi) \cap \partial X. \end{aligned}$$

Proposition 6.6. *Suppose that $u \in x^{-\delta} L^2$ for all $\delta > 0$ and $[\Delta - \alpha_0^2 \zeta(n - \zeta)]u \in \dot{C}^\infty(X)$. If u also satisfies the radiation condition $(x\partial_x - \sigma)u \in x^\epsilon L^2$ for $\epsilon > 0$, then*

$$\chi u(x, y) \in \mathcal{A}_{\sigma_{reg}}(X),$$

where χ, σ_{reg} satisfy (6.15).

Proof. Let $P_\zeta = [\Delta - \alpha_0^2 \zeta(n - \zeta)]$ with locally defined right parametrix M_ζ as in Proposition 4.3. For notational convenience we'll consider only the global case, since the introduction of cutoff functions for the local case is a simple matter.

Assume u is as stated. The idea is to apply the transpose of the equation $P_\zeta M_\zeta = 1 - E_\zeta$ to u . To justify this requires integration by parts, and this is where the radiation condition comes in. Consider the real pairing

$$\int (P_\zeta M_\zeta \phi) u \, dg$$

for arbitrary $\phi \in x^\epsilon L^2$. If the integral is cutoff at $x = s$, then we can transfer P_ζ to u , picking up a boundary term:

$$(6.16) \quad \int_{x \geq s} P_\zeta (M_\zeta \phi) u \, dg = \int_{x \geq s} (M_\zeta \phi) P_\zeta u \, dg - \int_{x=s} [M_\zeta \phi \cdot x \partial_x u - u \cdot x \partial_x (M_\zeta \phi)] \alpha x^{-n} dh.$$

Let $F(s)$ denote the boundary correction from the right-hand side of (6.16). The radiation condition tells us that $(x\partial_x - \sigma)u \in x^\epsilon L^2$, and by the structure of M_ζ and Lemma 4.1 we have also $(x\partial_x - \sigma)M_\zeta \phi \in x^\epsilon L^2$. Thus the expression in brackets in F lies in $x^{\epsilon-\delta} L^1(dg)$, because the leading terms cancel each other. In other words

$$\int_0^\infty s^{\gamma-\epsilon} |F(s)| \frac{ds}{s} < \infty,$$

which implies $\lim_{s \rightarrow 0} F(s) = 0$ because we can assume $\gamma < \epsilon$.

To transfer $M_\zeta \phi$ to $M_\zeta^t u$, requires only Fubini's theorem, and so we have

$$\int P_\zeta(M_\zeta \phi) u \, dg = \int \phi M_\zeta^t P_\zeta u \, dg.$$

Substituting $P_\zeta M_\zeta = I - E_\zeta$ in the left-hand integral then gives

$$\int \phi(I - E_\zeta^t) u \, dg = \int \phi M_\zeta^t P_\zeta u \, dg.$$

Since these properties hold for any $\phi \in x^\epsilon L^2$, we conclude that

$$u = M_\zeta^t P_\zeta u + E_\zeta^t u.$$

Note that $P_\zeta u \in \dot{C}^\infty(X)$, so $M_\zeta^t P_\zeta u \in \mathcal{A}_\sigma(X)$ by Lemma 4.1. Also $E_\zeta^t \in \Psi_{\sigma_l, \infty}(X)$ so we can show $E_\zeta^t u \in \mathcal{A}_\sigma(X)$ by moving derivatives under the integral. Hence $u \in \mathcal{A}_\sigma(X)$ as claimed. \square

Combine Propositions 6.5 and 6.6 gives the full limiting absorption result:

Theorem 6.7. *Let $\operatorname{Re} \zeta = n/2$ and $f \in \dot{C}^\infty(X)$. The limiting absorption principle defines a unique function $R_\zeta f$ solving*

$$[\Delta - \alpha_0^2 \zeta(n - \zeta)] R_\zeta f = f,$$

such that $\chi R_\zeta f \in \mathcal{A}_{\sigma_{reg}}(X)$ for any χ , σ_{reg} as in (6.15).

7. SCATTERING MATRIX FOR THE IRREGULAR CONTINUOUS SPECTRUM

Fix a ζ such that $\lambda = \alpha_0^2 \zeta(n - \zeta) \in (\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_1^2 n^2}{4}]$. Given a function $f \in \dot{C}^\infty(W_\lambda)$, by Corollary 3.3 we can find u_1 such that $(\Delta - \lambda)u_1 = \phi \in \dot{C}^\infty(X)$ and $\chi u_1 \in \mathcal{A}_{n-\sigma_{reg}}(X)$ with $x^{n-\sigma} f(y)$ as the leading term in the boundary expansion near W_λ . (Here χ, σ_{reg} are defined as in (6.15).) Then $R_\zeta \phi$ is defined by Theorem 6.7 and $u = u_1 - R_\zeta \phi$ satisfies $(\Delta - \lambda)u = 0$. We thus have proven:

Proposition 7.1. *For ζ as above, given $f \in \dot{C}^\infty(W_\lambda)$, there is a unique solution u of*

$$(\Delta - \lambda)u = 0,$$

with $\chi u \in \mathcal{A}_{n-\sigma_{reg}}(X) + \mathcal{A}_{\sigma_{reg}}(X)$ and

$$u \sim x^{n-\sigma} f + x^\sigma f' \text{ near } W_\lambda,$$

where $f' \in C^\infty(W_\lambda)$. Thus the map $f \mapsto f'$ defines a scattering matrix

$$S_\zeta : \dot{C}^\infty(W_\lambda) \rightarrow C^\infty(W_\lambda).$$

This result shows also that outside W_λ there is no scattering. On $\operatorname{supp}(\chi) \setminus W_\lambda$ we have $\operatorname{Re} \sigma_{reg} > n/2$, and $\operatorname{Im} \sigma_{reg} = 0$, for any χ, σ_{reg} . So the generalized eigenfunctions are L^2 near $\partial X \setminus \overline{W_\lambda}$, and there is no incoming/outgoing distinction to be made.

The limiting absorption principle itself tells nothing of the structure of R_ζ or S_ζ . In this section we will combine the local parametrix construction with limiting absorption to obtain more information on the Poisson and scattering kernels. As one would expect, the local structure of these kernels near W_λ is the same as in the case $\zeta \in \mathbb{C} \setminus \Gamma$ studied in §5.

Without any restrictions on the set $\{\alpha^2 = \frac{4\lambda}{n^2}\}$, one can't really hope to resolve the singularities of σ and construct the full resolvent. In this section we'll continue to work in full generality and just focus on the scattering kernel. The idea will be to mimic the construction of the Poisson kernel in §5, but starting from the local parametrix instead of the resolvent.

By Proposition 4.3, we have a local parametrix $M_\zeta = A_\zeta + B_\zeta$ solving the equation

$$(\Delta - \lambda)(A_\zeta + B_\zeta) = 1 - E_\zeta,$$

in a neighborhood of $W_\lambda \times W_\lambda$, where

$$\begin{aligned} A_\zeta &\in {}^0\Psi^{-2}(X), \\ B_\zeta &\in {}^0\Psi_{\sigma_l, \sigma_r}(X), \\ E_\zeta &\in \Psi_{\infty, \sigma_r}(X). \end{aligned}$$

Let us state this precisely using cutoffs. Fix $G \subset X$ with $G \cap \partial X \subset\subset W_\lambda$ and let χ_1, χ_2 be smooth functions whose supports intersect ∂X inside W_λ such that $\chi_1 = \chi_2 = 1$ on G . If we let these act as multiplication operators, we have

$$(7.1) \quad (\Delta - \lambda)\chi_1(A_\zeta + B_\zeta)\chi_2 = \chi_1(1 - E_\zeta)\chi_2 + [\Delta, \chi_1]A_\zeta\chi_2 + [\Delta, \chi_1]B_\zeta\chi_2.$$

By making the support of one cutoff fit inside the other, we are free to assume that $\chi_2 \cdot d\chi_1 = 0$. Recall that by construction A_ζ can be supported in an arbitrarily narrow neighborhood of the (lifted) diagonal. So by manipulating these assumptions, we can ensure that

$$[\Delta, \chi_1]A_\zeta\chi_2 = 0.$$

As in §5, we identify operators with their kernels using the Riemannian density. The restriction map used to obtain the Poisson kernel there was

$$r : k(x, y, x', y') \mapsto x'^{-\sigma(y')} k(x, y, x', y')|_{x'=0},$$

which we now want to apply to (7.1). Actually, we'll want to consider the restriction in terms of the lifts of distributions to $X \times_0 X$ and $X \times_0 \partial X$.

A_ζ vanishes to infinite order at the right face, so $r(A_\zeta) = 0$. The kernel of the multiplication operator $\chi_1\chi_2$ lives on the lifted diagonal, and so also $r(\chi_1\chi_2) = 0$. For the residual term we immediately conclude

$$(7.2) \quad r(\chi_1 E_\zeta \chi_2) \in \dot{C}^\infty(X \times \partial X)$$

Note that because $\tilde{\sigma}_l$ is an extension of the indicial root off the left face, we have

$$(\Delta - \lambda)\chi_1 B_\zeta \chi_2 \text{ and } \chi_1(\Delta - \lambda)B_\zeta \chi_2 \in \mathcal{A}_{\sigma_l|1, \sigma_r, 0},$$

implying also

$$[\Delta, \chi_1]B_\zeta \chi_2 \in \mathcal{A}_{\sigma_l|1, \sigma_r, 0}.$$

By the choice of supports, $[\Delta, \chi_1]\chi_2 = 0$, so $[\Delta, \chi_1]B_\zeta \chi_2$ is cutoff near the diagonal in $X \times X$, which makes the behavior of B_ζ at the front face irrelevant. Hence

$$(7.3) \quad r([\Delta, \chi_1]B_\zeta \chi_2) \in \mathcal{A}_{\sigma|1}(X \times \partial X).$$

Here we should to use σ_{reg} as in (6.15), but we'll drop the subscript for the rest of this argument.

Finally we set

$$M_\zeta = r(\chi_1 B_\zeta \chi_2).$$

which is the proposed parametrix of the Poisson kernel. Using (7.2) and (7.3) in (7.1) gives the result

$$(7.4) \quad (\Delta - \lambda)M_\zeta = F_\zeta \in \mathcal{A}_{\sigma|1}(X \times \partial X).$$

Note that the support of F_ζ meets the boundary of $X \times \partial X$ only in $W_\lambda \times W_\lambda$. The error term can be improved by solving away the boundary expansion of F_ζ as in Lemma 3.2 (with y' as an extra parameter). We thereby find $M'_\zeta \in \mathcal{A}_{\sigma|1}(X \times \partial X)$ such that

$$(\Delta - \lambda)M'_\zeta - F_\zeta = F'_\zeta \in \dot{C}^\infty(X \times \partial X).$$

Finally, Theorem 6.7 can be applied to remove the error term F'_ζ , again with y' as a parameter. This gives us

$$M''_\zeta = -R_\zeta F'_\zeta,$$

with $\chi_1 M''_\zeta \chi_2 \in \mathcal{A}_\sigma(X \times \partial X)$. Then, setting $E_\zeta = M_\zeta - M'_\zeta + M''_\zeta$, we have

$$(7.5) \quad (\Delta + \lambda)E_\zeta = 0.$$

Note that the structure of E_ζ is not determined near regions of the boundary where $\alpha^2 = \frac{n^2\lambda}{4}$.

The action of E_ζ on a function $f \in \dot{C}^\infty(W_\lambda)$ is given by

$$E_\zeta f(x, y) = \int_{W_\lambda} E_\zeta(x, y, y') f(y') dh_0(y').$$

This clearly yields a function smooth in the interior of X . To see that it is the Poisson kernel, we need only study its asymptotic expansion at the boundary near W_λ . However, if we apply a cutoff then $\chi_1 E_\zeta f$ has the same structure as in the global case considered in §5. By the argument used in that section we have:

Theorem 7.2. *For $\lambda = \alpha_0^2 \zeta(n - \zeta) \in (\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_1^2 n^2}{4}]$, the the Poisson kernel on W_λ (with respect to the Riemannian density of h_0) is*

$$\frac{1}{B(\sigma)\sqrt{h_0}} E_\zeta.$$

The scattering matrix $S_\zeta : \dot{C}^\infty(W_\lambda) \rightarrow C^\infty(W_\lambda)$ is a pseudodifferential operator with principal symbol

$$2^{n-2\sigma} \frac{\Gamma(\frac{n}{2} - \sigma)}{\Gamma(\sigma - \frac{n}{2})} |\xi|_{h_0}^{2\sigma-n}$$

8. RESOLVENT FOR THE IRREGULAR CONTINUOUS SPECTRUM

We now turn to the question of the structure of the resolvent in the irregular part of the continuous spectrum. In this section we will fix ζ such that $\lambda = \alpha_0^2 \zeta(n - \zeta) \in (\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_1^2 n^2}{4})$ and undertake a direct construction of the resolvent. Since analytic continuation is not available, we will still rely on the limiting absorption principle to prove existence of an inverse $R_\zeta = (\Delta - \lambda)^{-1}$ on the appropriate space. The structure of the R_ζ will be revealed by finding a sufficiently good parametrix. Construction the parametrix requires resolution of the singularities of σ , which is possible only if the singular set is sufficiently nice. Henceforth we make the assumption:

$$(8.1) \quad \frac{2\sqrt{\lambda}}{n} \text{ is a regular value of } \alpha,$$

which of course holds for generic λ by Sard's Theorem. Under this assumption the *crossover region*,

$$\Lambda = \{y : \alpha^2 = \frac{n^2\lambda}{4}\} = \{y : \sigma = \frac{n}{2}\} \subset \partial X$$

(i.e. the singular set of σ), is a regular hypersurface in ∂X .

Away from Λ we already have a parametrix, so we will only be concerned with local coordinates covering neighborhoods of Λ . For notational convenience we always choose the coordinate y_n to be a particular defining function of Λ :

$$(8.2) \quad y_n = \frac{\lambda}{\alpha^2} - \frac{n^2}{4}.$$

Within the coordinate neighborhood the indicial root depends solely on y_n ,

$$\sigma(y) = \frac{n}{2} + \sqrt{-y_n}.$$

As in §6, we introduce an extension $\tilde{\sigma}$ which locally has the form

$$(8.3) \quad \tilde{\sigma}(x, y) = \frac{n}{2} + \sqrt{ix - y_n},$$

near $y_n = 0$. The ix term can be cutoff outside of a neighborhood of Λ in some arbitrary way that we won't bother to notate.

8.1. Crossover blow-up. The singularity of $\tilde{\sigma}$ is resolved by the blow-up

$$X_\lambda = [X; \Lambda].$$

To form X_λ from X , Λ is replaced by the *crossover face*

$$\tilde{\Lambda} = SN(\Lambda) \simeq \Lambda \times S_+^1.$$

Under our convention for local coordinates (8.2), the blow-up just amounts to the introduction of polar coordinates centered at the origin in the (x, y_n) half-plane. Since $\partial X \setminus \Lambda$ is the set on which σ is smooth, we will refer to the lift of this set to X_λ as the *regular face*. The lift of $\tilde{\sigma}$ to X_λ will be denoted again by $\tilde{\sigma}$.

Projective coordinates show how the blow up resolves the singularity of $\tilde{\sigma}$. In the interior of the crossover face we can use coordinates $x, w = y_n/x$. Thus

$$\tilde{\sigma} = \frac{n}{2} + x^{1/2} \sqrt{i - w},$$

which is homogeneous in x with a coefficient smooth in the interior of $\tilde{\Lambda}$. To handle the corners on either side of the face we use the coordinates $y_n, s = \pm x/y_n$. For $y_n > 0$, for example, we have

$$\tilde{\sigma} = \frac{n}{2} + y_n^{1/2} \sqrt{is - 1}.$$

This is smooth up to the regular face $s = 0$, and again homogeneous at the crossover face.

To define the space of polyhomogeneous conormal functions of order σ we can't just appeal to Definition 2.1, because σ is not a smooth function on the regular face. (It takes the constant value $\frac{n}{2}$ on the crossover face, so no problem there.) Fortunately, the square-root singularity in σ is comparatively mild, and the only change needed in the definition from §2 is to make the asymptotic expansion at the crossover face decrease by half-integer powers rather than integer.

Let us choose boundary defining functions ρ_1, ρ_2 for X_λ and radial vector fields $V_1, V_2 \in \mathcal{V}_b(X_\lambda)$, where the faces are ordered regular, crossover.

Definition 8.1. $\mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ consists of $u \in C^\infty(X^\circ)$ such that for any $m_1, m_2 \in \mathbb{N}_0$ we have

$$\left[\prod_{k=0}^{m_1-1} (V_1 - k)^{k+1} \prod_{l=0}^{m_2-1} (V_2 - l/2)^{\kappa_l+1} \right] (x^{-\tilde{\sigma}} u) \in \mathcal{A}^{(m_1, m_2/2)-}(X_\lambda),$$

for some sequence $\kappa_l \in \mathbb{N}_0$ with $0 = \kappa_0 < \kappa_1 < \dots$.

The brackets in the notation $\mathcal{A}_{\sigma, [\frac{n}{2}]}$ are meant to reflect both the half-step expansion and the extra growth of logarithmic powers represented by $\{\kappa_l\}$. Applying the same reasoning as in Proposition 2.2, we see that u has asymptotic expansion as usual at the regular face, but at the crossover face powers grow by half-steps:

$$(8.4) \quad x^{-\tilde{\sigma}} u \sim \sum_{l=0}^{\infty} \sum_{j \leq \kappa_l} \rho_2^{l/2} (\log \rho_2)^j a_{l,j} \text{ near } \tilde{\Lambda}.$$

As in §2 we define spaces with truncated expansions at the regular face by

$$\mathcal{A}_{\sigma[k, \frac{n}{2}]}(X_\lambda) = (\rho_1 \log \rho_1)^k \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda).$$

For the crossover face it will prove more convenient to use the notation $[\frac{n+k}{2}]_+$, where $[a]_+$ indicates that $\rho_2^{-a} u$ has an expansion of the form (8.4), but with $\kappa_0 > 0$.

The extension $\tilde{\sigma}$ depends of course on the choice of x , but the notation $\mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ is meant to reflect the fact that the space is independent of this choice.

Lemma 8.2. *The space $\mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ does not depend on the choice of coordinate x used to define the extension $\tilde{\sigma}$ in (8.3).*

Proof. A different choice of boundary defining function could always be written $x\phi$, where $\phi \in C^\infty(X)$ and is strictly positive. Thus we are concerned with the difference

$$\sqrt{ix\phi - y_n} - \sqrt{ix - y_n} = \rho_1 \sqrt{\rho_2} f,$$

for $f \in C^\infty(X_\lambda)$. For simplicity we can assume $\rho_1 \rho_2 = x$, so that we want to show that

$$(\rho_1 \rho_2)^{(\rho_1 \sqrt{\rho_2} f)} \cdot \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda) \subset \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda).$$

We use an induction similar to the proof of Lemma 2.3. Defining the commutators

$$Z_{q_1, q_2} = \left[\prod_{k=0}^{q_1-1} (V_1 - k)^{k+1} \prod_{l=0}^{q_2-1} (V_2 - l/2)^{\kappa_l+1}, (\rho_1 \rho_2)^{(\rho_1 \sqrt{\rho_2} f)} \right],$$

the result will follow if we can show

$$Z_{q_1, q_2} : \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda) \rightarrow \mathcal{A}_{\sigma|_{q_1, [(n+q_2)/2]_+}}(X_\lambda).$$

The operators $Z_{1,0}$ and $Z_{0,1}$ are functions that act by multiplication, and a simple computation shows that

$$Z_{1,0} \in (\rho_1 \log \rho_1) \sqrt{\rho_2} (\rho_1 \rho_2)^{(\rho_1 \sqrt{\rho_2} f)} \cdot C^\infty(X_\lambda),$$

and

$$Z_{0,1} \in (\sqrt{\rho_2} \log \rho_2) \rho_1 (\rho_1 \rho_2)^{(\rho_1 \sqrt{\rho_2} f)} \cdot C^\infty(X_\lambda),$$

so the mapping result holds for these cases by the characterization in terms of asymptotic expansions.

The inductive step follows precisely as in Lemma 2.3, once we note that

$$\begin{aligned} Z_{1,0} : \mathcal{A}_{\sigma|_{q_1, [(n+q_2)/2]_+}}(X_\lambda) &\rightarrow \mathcal{A}_{\sigma|_{(q_1+1), [(n+q_2)/2]_+}}(X_\lambda) \\ Z_{0,1} : \mathcal{A}_{\sigma|_{q_1, [(n+q_2)/2]_+}}(X_\lambda) &\rightarrow \mathcal{A}_{\sigma|_{q_1, [(n+q_2+1)/2]_+}}(X_\lambda) \end{aligned}$$

□

Lemma 8.3. *The space $\mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ is preserved under the action of lifts of vector fields from $\mathcal{V}_0(X)$ to X_λ .*

Proof. It is easy to verify that vector fields in $\mathcal{V}_0(X)$ lift to vector fields in $\mathcal{V}_b(X_\lambda)$ by considering local coordinates. For example, in the interior of the crossover face the coordinates $x, w = y_n/x$ are valid. The lifts of the vector fields $x\partial_x$ and $x\partial_{y_n}$ to X_λ are

$$\begin{aligned} x\partial_x &\longrightarrow x\partial_x - w\partial_w \\ x\partial_{y_n} &\longrightarrow \partial_w \end{aligned}$$

At the boundary of the regular and crossover faces, we use coordinates $y_n, t = x/y_n$, and the lifts are

$$\begin{aligned} x\partial_x &\longrightarrow t\partial_t \\ x\partial_{y_n} &\longrightarrow y_n t \partial_{y_n} - t^2 \partial_t \end{aligned}$$

The lemma follows immediately from the invariance of $\mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ under $\mathcal{V}_b(X_\lambda)$. □

The proof of Lemma 8.3 reveals one of the complications of introducing X_λ . The lifts of vector fields from $\mathcal{V}_0(X)$ vanish at the regular face, but are only tangent to the crossover face. Thus the indicial equation, which defined σ in the first place, is not valid on X_λ . To put this another way, the highest order terms in $(\Delta - \lambda)x^\sigma f$ cancel out if $f \in C^\infty(X)$ but not for $f \in C^\infty(X_\lambda)$. Thus the analog of Corollary 3.3 in this context is:

Proposition 8.4. *Given $f \in C^\infty(\partial X)$ can find $u \in \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ satisfying*

$$(\Delta - \lambda)u \in \mathcal{A}_{\infty, [\frac{n+1}{2}]_+}(X_\lambda)$$

(for ζ such that λ satisfies (8.1)), so that $x^{\tilde{\sigma}}f$ gives the leading term in the asymptotic expansions of u at both the regular or crossover faces.

Proof. Extending f smoothly into the interior in some arbitrary way, we have

$$(\Delta - \lambda)x^{\tilde{\sigma}}f \in \mathcal{A}_{\sigma|1, [\frac{n+1}{2}]_+}(X_\lambda),$$

because σ is the indicial root. As in the proof of Lemma 8.3, let us use coordinates $y_n, t = x/y_n$. By the lifts of vector fields computed there we see that

$$\begin{aligned} (\Delta - \lambda)t^{\tilde{\sigma}+k}(\ln t)^l a_{k,l} &= \alpha^2 k(n - 2\tilde{\sigma} - k)t^{\tilde{\sigma}+k}(\ln t)^l a_{k,l} \\ &\quad + t^{\tilde{\sigma}+k}(\ln t)^l \left[\sqrt{y_n}(t \ln t)g_1 + tg_2 + y_n(t \ln t)^2 g_3 \right], \end{aligned}$$

where $g_1, g_2, g_3 \in C^\infty(X_\lambda)$. This shows that the asymptotic expansion of $(\Delta - \lambda)x^{\tilde{\sigma}}f$ at the regular face may be solved away exactly as in Lemma 3.2, giving u as stated. \square

8.2. Normal operator. An essential tool in the Mazzeo-Melrose construction of the resolvent [13] is the normal operator defined by restricting a kernel to the front face of $X \times_0 X$. The definition is most conveniently made using half-densities. In particular they allow us to easily write local formulas for invariant expressions. The Riemannian half-density on X determined by g is a smooth section of the singular density bundle $\Omega_0^{1/2} = x^{-(n+1)/2}\Omega^{1/2}$, where Ω is the density bundle. By the same convention we define $\Omega_0^{1/2}(X \times X) = (xx')^{-(n+1)/2}\Omega$. We'll also let $\Omega_0^{1/2}(X \times_0 X)$ denote the lift of $\Omega_0^{1/2}(X \times X)$ to the stretched product. The Laplacian on half-densities is defined by

$$\hat{\Delta}(f\mu_g^{1/2}) = (\Delta f)\mu_g^{1/2},$$

where μ_g is the Riemannian density. We'll work with half-densities for the rest of this section. Operators will be assumed to act on $C^\infty(X; \Omega_0^{1/2})$, so their kernels are naturally interpreted as distributional half-densities in $C^{-\infty}(X \times X; \Omega_0^{1/2})$.

Let F be the front face of $X \times_0 X$, and for $q \in \partial X$ let F_q be the fiber of F over q . If K is an operator in

$${}^0\Psi_{\sigma_l, \sigma_r}^m(X; \Omega_0^{1/2}) = {}^0\Psi^m(X; \Omega_0^{1/2}) + {}^0\Psi_{\sigma_l, \sigma_r}(X; \Omega_0^{1/2}),$$

then the normal operator of K at q is

$$N_q(K) = \beta^* K|_{F_q} \in {}^0\Psi_{\sigma(q), \sigma(q)}^m(F_q; \Omega_0^{1/2}(X \times_0 X)|_{F_q}).$$

The key fact here is that the F_q can be identified with the group of boundary preserving linear transformations of $X_q = T_q^+ X$, while the restriction of $\Omega_0^{1/2}(X \times_0 X)$ to F_q is naturally identified with $\Omega_0^{1/2}(X_p \times X_p)$. Thus $N_q(K)$ acts naturally as a convolution operator

$$N_q(K) : \dot{C}^\infty(X_q; \Omega_0^{1/2}) \rightarrow C^{-\infty}(X_q; \Omega_0^{1/2}).$$

To write this map down concretely, let (x, y, x', y') be the coordinates on $X \times X$. For $X \times_0 X$ we use x, y and the projective coordinates $t = x/x', u = (y - y')/x'$. Fixing a base point $q = (0, y_0) \in \partial X$, (t, u) become coordinates for the fiber F_q . It is convenient to give X_q the coordinates x, y given by linearizing the functions x and y . The action of F_q on X_q can then be written

$$(x, y) \cdot (t, u)^{-1} = \left(\frac{x}{t}, y - \frac{x}{t}u \right).$$

We'll introduce reference half-forms $\mu = \left| \frac{dx dy}{x^{n+1}} \right|^{1/2}$, as a section of $\Omega_0^{1/2}(X_q)$, and

$$\gamma = \left| \frac{dx dy dt du}{x^{n+1}t} \right|^{1/2} \in C^\infty(X \times_0 X; \Omega_0^{1/2}).$$

Let β^*K be given locally by $k(x, y, t, u) \cdot \gamma$. Then the convolution action of the normal operator is

$$N_q(K)(f \cdot \mu) = \int k(0, y_0, t, u) f\left(\frac{x}{t}, y - \frac{x}{t}u\right) \frac{dt du}{t} \cdot \mu,$$

where $f \in C^\infty(X_q)$.

The usefulness of this definition rests on the following facts. Let $\text{Diff}_0^m(X)$ be the space of differential operators on X generated by \mathcal{V}_0 . If $\text{Diff}_0^m(X; \Omega_0^{1/2})$ is the corresponding space of operators on half-densities, then we can naturally regard $\text{Diff}_0^m(X; \Omega_0^{1/2})$ as a subspace of ${}^0\Psi_{\infty, \infty}^m(X \times_0 X; \Omega_0^{1/2})$.

Lemma 8.5. [13] *For $P \in \text{Diff}_0^m(X; \Omega_0^{1/2})$ the normal operator $N_q(P)$ is given by “freezing coefficients” at q . That is, for*

$$P(f \cdot \mu) = \sum_{k+|\alpha| \leq m} p_{k, \alpha}(x, y) (x \partial_x)^k (x \partial_y)^\alpha f \cdot \mu,$$

we have (abusing notation by using the same coordinates for X and X_q):

$$N_q(P)(f \cdot \mu) = \sum_{k+|\alpha| \leq m} p_{k, \alpha}(0, y_0) (x \partial_x)^k (x \partial_y)^\alpha f \cdot \mu.$$

Moreover, if $K \in {}^0\Psi_{a, b}^\infty(X \times_0 X; \Omega_0^{1/2})$,

$$(8.5) \quad N_q(PK) = N_q(P) \cdot N_q(K).$$

8.3. Crossover stretched product. To construct the resolvent when σ has singularities, we must combine the stretched product with the blow-up of Λ in §8.1. To understand what is needed here, we recall some facts from the general theory developed in Chapter 5 of [15]. A p -submanifold Z of a manifold with corners M is a submanifold such that near each point of Z there are coordinates $(x, y) \in \mathbb{R}_+^k \times \mathbb{R}^{m-k}$ for M such that locally

$$Z = \{x_{l+1} = \cdots = x_k = 0, y_{k+j+l} = \cdots = y_m = 0\}$$

(‘p’ stands for product). All of the submanifolds we want to blow up will be p-submanifolds. If Z and Y are p-submanifolds of M then the lift of Z to $[M; Y]$ through the blow-down map $\beta : [M; Y] \rightarrow M$ is defined in two distinct cases:

$$\beta^*Z = \begin{cases} \beta^{-1}Z & \text{if } Z \subset Y, \\ \beta^{-1}(Z \setminus Y) & \text{if } Z = \overline{Z \setminus Y}. \end{cases}$$

Assuming that the lift β^*Z is a p-submanifold of $[M; Y]$, we can define the double blow-up $[M; Y; Z]$ as $[[M; Y]; \beta^*Z]$.

Lemma 8.6. [15] *The double blow-ups $[M; Y; Z]$ and $[M; Z; Y]$ are well-defined and naturally diffeomorphic by the unique extension of the identity map on the interior under the following conditions:*

1. Y is a p -submanifold of M and Z is a p -submanifold of Y .
2. Y and Z are p -submanifolds of M meeting transversally.

In $X \times X$ the submanifolds needing to be resolved are $S = \{x = x' = y - y' = 0\}$, $\Lambda_l = \{x = y_n = 0\}$, and $\Lambda_r = \{x' = y'_n = 0\}$. In order to make a symmetric definition we first need to blow-up the intersection

$$\Lambda_f = \Lambda_l \cap S = \Lambda_r \cap S = \{x = x' = y - y' = y_n = 0\}.$$

FIGURE 5. Copies of the crossover set in $X \times_0 X$ are blown up to form $X \times_\lambda X$.

The *crossover stretched product* is

$$(8.6) \quad X \times_\lambda X = [X \times X; \Lambda_f; S; \Lambda_l; \Lambda_r].$$

There are many equivalent ways to order the blow-ups, though not all possibilities are permitted. For example, since $\Lambda_f \subset S$, we can interchange the first two blow-ups and write $X \times_\lambda X = [X \times_0 X; \Lambda_f; \Lambda_l; \Lambda_r]$. This is illustrated in Figure 5. The crossover stretched product has six faces. The left and right faces of $X \times X$ lift to *left* and *right regular faces*, and the lift of S is the *front regular face*. The lifts of $\Lambda_f, \Lambda_l, \Lambda_r$ are the *front, left* and *right crossover faces*, respectively.

The lift of S to $[X \times X; \Lambda_f]$ does not intersect the lifts of Λ_l and Λ_r , and the intersection of Λ_l with Λ_r is clearly transverse. Thus in (8.6) the last three blow-ups may be taken in any order. Because of this there are natural projections $X \times_\lambda X \rightarrow X_\lambda$ through the right and left factors. To project on the left, for example, we can first blow down Λ_r and S to get $[X \times X; \Lambda_f; \Lambda_l]$. Then because $\Lambda_f \subset \Lambda_l$ we can interchange these two blow-ups and blow down Λ_f , leaving $[X \times X; \Lambda_l] = X_\lambda \times X$. Finally we project onto X_λ to give the full map.

To describe expansions at the crossover faces we will continue to use the notations $[a]$ and $[a]_+$ introduced in §8.1. The full set of boundary information for the faces will be given as an *index family*. For example, let $\mathcal{M} = (\sigma_l, \sigma_r, 0, [\frac{n}{2}], [\frac{n}{2}], [0])$, where the order is left, right, front regular, then left, right, front crossover. The space $\mathcal{A}_\mathcal{M}(X \times_\lambda X)$ is defined analogously to $\mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ in Definition 2.1, using extensions $\tilde{\sigma}_l, \tilde{\sigma}_r$ which are lifts of $\tilde{\sigma}$. By the same arguments from §8.1 we have:

Lemma 8.7. $\mathcal{A}_\mathcal{M}(X \times_\lambda X)$ is well-defined independently of the choice of extensions of σ_l and σ_r and is invariant under $\mathcal{V}_b(X \times_\lambda X)$.

Truncated expansions at the regular faces will be notated as before, by replacing σ_l with $\sigma_l|k$.

We continue to use $\Omega_0^{1/2}$ to denote the half-density bundle spanned by the Riemannian half-density on X (and lifts and combinations thereof). For example, $\Omega_0^{1/2}(X_\lambda)$ denotes the lift of $\Omega_0^{1/2}(X)$ to X_λ . If ρ, s are defining functions for the regular and crossover faces, respectively, then

$$\Omega_0^{1/2}(X_\lambda) = \rho^{-\frac{n+1}{2}} s^{-\frac{n}{2}} \Omega^{1/2}(X_\lambda).$$

The formula for $\Omega_0^{1/2}(X \times_\lambda X)$ is similar.

Abusing notation slightly, we write $A \in \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2})$ for an operator on sections of $\Omega_0^{1/2}(X)$, meaning that the distribution kernel of A lifts to an element of this space.

The front regular face still fibers over the regular face of X_{λ} , and there the definition and properties of the normal operator are unchanged. However, we will not be able to use this construction at the front crossover face, beyond the first iteration.

Proposition 8.8. *For ζ such that $\lambda = \alpha_0^2 \zeta(n - \zeta) \in (\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_1^2 n^2}{4})$, there exists a parametrix W for $\hat{\Delta} - \lambda$ such that*

$$(\hat{\Delta} - \lambda)W = I - F$$

where

$$\begin{aligned} W &\in {}^0\Psi^{-2}(X; \Omega_0^{1/2}) + \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2}), \\ F &\in \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}), \end{aligned}$$

with $\mathcal{M} = (\sigma_l, \sigma_r, 0, [\frac{n}{2}], [\frac{n}{2}], [0])$ and $\mathcal{F} = (\infty, \sigma_r, \infty, [\frac{n+1}{2}]_+, [\frac{n}{2}], [\frac{1}{2}]_+)$

Proof. The first part of the construction is the symbolic inversion along the lifted diagonal in $X \times_0 X$. This does not involve σ and so can be done just as in [13]. We obtain $A \in {}^0\Psi^{-2}(X; \Omega_0^{1/2})$ such that

$$(\hat{\Delta} - \lambda)A - I = Q \in {}^0\Psi^{-\infty}(X; \Omega_0^{1/2}).$$

The kernel of Q , lifted to $X \times_0 X$, lies in $\rho^{\infty} \rho'^{\infty} C^{\infty}(X \times_0 X; \Omega_0^{1/2})$. The next step in the construction is to try to solve away this error term at the front face.

To this end, we seek an operator B_0 such that

$$(8.7) \quad N(\hat{\Delta} - \lambda)N(B_0) = N(Q).$$

Here $N_p(Q) \in \dot{C}^{\infty}(F_p)$. For $p \in \partial X$,

$$N_p(\hat{\Delta} - \lambda) = \alpha^2(p) \Delta_{\beta_p} - \lambda,$$

where β_p is the metric on X_p given by

$$\beta_p = \frac{dx^2 + h_p}{x^2},$$

with h_p the constant tensor on X_p defined by the restriction of h to $T_p^+ X$. Since h_p is constant, β_p is the pull-back of the standard hyperbolic metric on \mathbb{H}^{n+1} by a linear change of coordinates. Let

$$R_0(\beta_p; \eta) = [\hat{\Delta}_{\beta_p} - \eta(n - \eta)]^{-1}$$

denote the resolvent for this metric, which is just given by applying the linear coordinate change to the standard resolvent on \mathbb{H}^{n+1} . Noting that $\lambda/\alpha^2 = \sigma(n - \sigma)$, we set

$$N_p(B_0) = \frac{1}{\alpha^2(p)} R_0(\beta_p; \sigma(p)) N_p(Q).$$

For each p we have $N_p(B_0) \in \mathcal{A}_{\sigma(p), \sigma(p)}(F_p; \Omega_0^{1/2}|_{F_p})$. Although $N_p(Q)$ depended smoothly on p , $N_p(B_0)$ does not because of σ . So this is the first point at which we need the lift from $X \times_0 X$ to $X \times_{\lambda} X$. Let \tilde{S} denote the front regular face (the lift of S). Since the dependence of $N(B_0)$ on σ is analytic, the lift of $N(B_0)$ to \tilde{S} has a square root singularity at the crossover boundary coming from that of σ . Hence we have

$$N(B_0)|_{\tilde{S}} \in \mathcal{A}_{\sigma, \sigma, 0}(\tilde{S}; \Omega_0^{1/2}|_{\tilde{S}}),$$

where the boundaries of \tilde{S} are left/right regular and front crossover, and σ is lifted to \tilde{S} through the projection $\tilde{S} \rightarrow \partial X \setminus \Lambda$.

The front crossover face, denoted $\tilde{\Lambda}_f$, fibers over lift of Λ to the front face S in $X \times_0 X$. The lift of $N(B_0)$ from S to the front crossover face in $X \times_\lambda X$ will be constant on such fibers. Thus the lift of $N(B_0)$ has no singularity at the front regular boundary of $\tilde{\Lambda}$, and

$$N(B_0)|_{\tilde{\Lambda}_f} \in \mathcal{A}_{\sigma, \sigma, 0, [\frac{n}{2}], [\frac{n}{2}]}(\tilde{\Lambda}_f; \Omega_0^{1/2}|_{\tilde{\Lambda}_f}).$$

The boundary faces of $\tilde{\Lambda}_f$ are left/right/front regular and left/right crossover (see Figure 5).

By Proposition 2.2, this shows that the lift of $N(B_0)$ to $X \times_\lambda X$ has the properties of the restriction of a kernel in $\mathcal{A}_{\mathcal{M}}(X \times_\lambda X; \Omega_0^{1/2})$ to the two front faces. We may therefore choose an extension $B_0 \in \mathcal{A}_{\mathcal{M}}(X \times_\lambda X; \Omega_0^{1/2})$, having the lift of $N(B_0)$ as leading coefficient at these faces. Furthermore, since $N(B_0)$ was constant on fibers of the front crossover face, we can insist that the leading coefficient of B_0 at the left crossover face be constant on the fibers of this face as well.

The error term at the next stage is

$$Q_1 = (\hat{\Delta} - \lambda)B_0 - Q.$$

By construction, the kernel of Q_1 vanishes at the front face, so

$$Q_1 \in \mathcal{A}_{\mathcal{M}_1}(X \times_\lambda X; \Omega_0^{1/2}), \quad \mathcal{M}_1 = (\sigma_l, \sigma_r, 0|1, [\frac{n}{2}], [\frac{n}{2}], [\frac{1}{2}]_+).$$

However, there is additional decay on the front face, because σ is the indicial root. The composition $(\hat{\Delta} - \lambda)B_0$ has kernel given by lifting $\hat{\Delta} - \lambda$ to $X \times_\lambda X$ through the left and applying it to the kernel B_0 .

Consider local coordinates (t, z, x', \bar{y}, w) , where $t = \frac{x}{y_n}$, $z = \frac{y-y'}{x'}$, $w = \frac{y_n}{x'}$, and $\bar{y} = (y_1, \dots, y_{n-1})$. This system is valid in a neighborhood of the intersection $\tilde{L} \cap \tilde{\Lambda}_f \cap \tilde{\Lambda}_l$. The lift of vector fields through the left is easily computed:

$$\begin{aligned} x\partial_x &\longrightarrow t\partial_t \\ x\partial_{\bar{y}} &\longrightarrow wt\partial_{\bar{z}} + wx'\partial_{\bar{y}} \\ x\partial_{y_n} &\longrightarrow wt\partial_w - t^2\partial_t + wt\partial_{\bar{z}} \end{aligned}$$

Here t defines the left regular face, and w the left crossover. It is easy to compute that

$$\begin{aligned} (\beta_l^* \Delta - \lambda)(tw)^{\tilde{\sigma}_l + k} f &= \alpha^2 k(n - 2\sigma_l - k)(tw)^{\tilde{\sigma}_l + k} f \\ (8.8) \quad &+ (tw)^{\tilde{\sigma}_l + k} \left[(wx')^{1/2} (t \log tw) g_1 + wx' (t \log tw)^2 g_2 \right] f \\ &+ (tw)^{\tilde{\sigma}_l + k} tVf, \end{aligned}$$

where $g_1, g_2 \in C^\infty(X \times_\lambda X)$ and $V \in \text{Diff}_b^*(X \times_\lambda X)$. In particular, with $k = 0$ we see that $(\hat{\Delta} - \lambda)B_0$ vanishes at the left regular face.

At the left crossover face we have the same issue as in Proposition 8.4, because the final term on the right in (8.8) is not of lower order in w . More specifically, tVf contains terms of the form $(t\partial_t)^i f$ times smooth coefficients. However, in these coordinates t is the fiber variable for the left crossover face. Thus choosing B_0 to be constant on the fibers means that in the calculation of $(\hat{\Delta} - \lambda)B_0$ the term represented by tV does not contribute. We conclude that

$$\mathcal{M}_1 = (\sigma_l|1, \sigma_r, 0|1, [\frac{n+1}{2}]_+, [\frac{n}{2}], [\frac{1}{2}]_+).$$

At the front regular face we may iterate the procedure of solving away terms with the normal operator, exactly as in [13]. We would next apply the model resolvent to $N_p((x' \log x')^{-1} Q_1)$ (using Proposition 4.2 to handle the extra logarithms) and so obtain $N_p((x' \log x')^{-1} B_{1,1})$, from which we determine $B_{1,1}$, and so on. (We cannot do the same at the crossover face, because the derivatives along the fiber appearing in (8.8) cannot be assumed to vanish for any terms beyond B_0 . As a

result, we could not apply Proposition 4.2 to the higher Q_j 's because of the lack of decay at the left crossover face.)

After repeated applications of the normal operator at the front regular face we end up with a sequence $B_{j,l}$ which can be summed asymptotically to give $B \in \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2})$ such that

$$(\hat{\Delta} - \lambda)B - Q = G \in \mathcal{A}_{\mathcal{G}}(X \times_{\lambda} X; \Omega_0^{1/2}),$$

where $\mathcal{G} = (\sigma_l|1, \sigma_r, \infty, [\frac{n+1}{2}]_+, [\frac{n}{2}], [\frac{1}{2}]_+)$. Finally, to get F we can appeal to (8.8) repeatedly to solve away the power series at the left regular face, as in Proposition 8.4. This yields $C \in \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2})$ such that

$$(\hat{\Delta} - \lambda)C - G = F \in \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}),$$

where \mathcal{F} is as defined in the statement. Setting $W = A - B + C$ gives the result. \square

8.4. Compositions. To refine the parametrix W further, we would like to asymptotically sum the Neumann series for $(I - F)^{-1}$ and right multiply this by W . Analyzing the result requires some composition properties for operators of these types. Composition can always be broken down into a combination of pull-backs and push-forwards, and we need to be sure that the character of asymptotic expansions at the boundary under such operations.

Fortunately, general results on pull-back and push-forward of polyhomogeneous conormal functions were established in [14, 15]. We'll review briefly the results we need, which are all in the context of constant indices. Although one could extend this theory to polyhomogeneous functions with variable order, complications would arise because of the possible crossing of indices. We won't undertake this here, as the constant index theory is sufficient for our purposes.

To specify a general polyhomogeneous conormal function, we give an *index set* $E \subset \mathbb{C} \times \mathbb{N}_0$ at each boundary face, such that at this face the boundary expansion has the form

$$\sum_{(s,k) \in E} \sum_{l=0}^k t^a (\log t)^l a_{s,l},$$

where t is the defining function. To ensure a finite number of logarithmic terms at each stage it is required that for any sequence $(s_j, k_j) \in E$ with $|(s_j, k_j)| \rightarrow \infty$ we have $\operatorname{Re} s_j \rightarrow \infty$. It is convenient to write $\operatorname{Re} E > m$ to mean $\operatorname{Re} a > m$ for all $(a, k) \in E$. At this level of generality, an index family is a collection $\mathcal{E} = (E_1, E_2, \dots)$, one index set for each boundary face. The space $\mathcal{A}_{\mathcal{E}}(M)$ is defined just as in §2.

On a manifold with corners M one can associate to $\mathcal{V}_b(M)$ a corresponding tangent bundle bTM . A map $f : M_1 \rightarrow M_2$ induces ${}^bf_* : {}^bTM_1 \rightarrow {}^bTM_2$ by extension from the interior. Let r_j, ρ_j be defining functions for the boundary hypersurfaces of M_1 and M_2 respectively. The map f is called a *b-map* if there exist $e(i, j) \in \mathbb{N}_0$ such that

$$f^* \rho_i = h \prod r^{e(i,j)},$$

Actually, in all of our cases $e(i, j) \in \{0, 1\}$. The b-map condition is sufficient for pull-back of polyhomogeneity. For \mathcal{F} an index family for M_2 , let $f^\sharp(\mathcal{F}) = (E_1, E_2, \dots)$, where

$$E_j = \{(b, p) : b = \sum_i e(i, j) a_i, p = \sum_{e(i,j) \neq 0} k_i, (a_i, k_i) \in F_i\}.$$

Proposition 8.9. *For a b-map $f : M_1 \rightarrow M_2$, pull-back gives a map*

$$f^* : \mathcal{A}_{\mathcal{F}}(M_2) \rightarrow \mathcal{A}_{f^\sharp(\mathcal{F})}(M_1)$$

The proof is quite straightforward: one can push forward the radial vector fields from M_1 to M_2 .

Extra conditions are needed for push-forward of polyhomogeneity. A b-map $f : M_1 \rightarrow M_2$ is called a *b-fibration* if: (1) ${}^b f_*$ is surjective at each point of ∂M_1 ; and (2) no boundary hypersurface of M_1 is mapped to a corner of M_2 . The latter condition means for each j there is at most one i for which $e(i, j) \neq 0$. The b-density bundle is defined by $\Omega_b = (\prod \rho_j)^{-1} \Omega$.

In push-forwards the powers of logarithms may increase when two or more faces map to the same face. So for two index sets E, F we define the *extended union*

$$E \cup F = E \cup F \cup \{(a, k + k' + 1) : (a, k) \in E, (a, k') \in F\}.$$

Then define $f_\#(\mathcal{E}) = (F_1, F_2, \dots)$, in the special case that all $e(i, j) \in \{0, 1\}$, by

$$F_i = \overline{\cup_{e(i, j) \neq 0} E_j}.$$

(If $e(i, j) > 1$ then the orders in E_j would be divided by $e(i, j)$.)

Proposition 8.10. *Let $f : M_1 \rightarrow M_2$ be a b-fibration and suppose that $\operatorname{Re} E_j > 0$ for all j such that $e(i, j) = 0$ for each i (i.e. for all j such that the j 'th boundary face maps to the interior). Then push-forward gives a map*

$$f_* : \mathcal{A}_{\mathcal{E}}(M_1; \Omega_b) \rightarrow \mathcal{A}_{f_\#(\mathcal{E})}(M_2; \Omega_b)$$

In order to compose operators whose kernels live naturally on $X \times_\lambda X$ we need to define a blown-up triple product $(X^3)_\lambda$ such that projections to $X \times_\lambda X$ through various factors exist and are b-fibrations. This is analogous to the edge triple product in [12]. The philosophy behind the construction is the same as in the definition of $X \times_\lambda X$. X^3 contains three copies each of S and Λ , but before blowing them up we must blow up any non-transverse intersections. It is perhaps easiest to describe this in local coordinates, which also make evident the fact that all submanifolds introduced are p-submanifolds. Corresponding to the usual (x, y) on X , we use (x, y, x', y', x'', y'') as local coordinates for X^3 . Let us label the three boundaries of X^3 as L, M, R for left, middle, and right. The three copies of S are

$$\begin{aligned} S_{LM} &= \{x = x' = y - y' = 0\}, \\ S_{MR} &= \{x' = x'' = y' - y'' = 0\}, \\ S_{LR} &= \{x = x'' = y - y'' = 0\}, \end{aligned}$$

and the copies of the crossover set are

$$\Lambda_L = \{x = y_n = 0\}, \quad \Lambda_M = \{x' = y'_n = 0\}, \quad \Lambda_R = \{x'' = y''_n = 0\}.$$

The intersections among the copies of Λ are transverse, but none of the intersections involving copies of S are. Additional blow-ups are needed for the triple intersections,

$$S_{LMR} = S_{LM} \cap S_{MR} \cap S_{LR}, \quad \Lambda_{LMR} = \Lambda_L \cap S_{LMR},$$

and double intersections

$$\Lambda_{LM} = \Lambda_L \cap S_{LM}, \quad \Lambda_{MR} = \Lambda_M \cap S_{MR}, \quad \Lambda_{LR} = \Lambda_L \cap S_{LR}.$$

The blown-up triple product is thus

$$(X^3)_\lambda = [X^3; \Lambda_{LMR}; S_{LMR}; \Lambda_{LM}; \Lambda_{MR}; \Lambda_{LR}; S_{LM}; S_{MR}; S_{LR}; \Lambda_L; \Lambda_M; \Lambda_R]$$

This gives a manifold with 14 faces. The faces will be denoted by putting a tilde over the corresponding submanifold of X^3 , e.g. \tilde{L} is the lift of $\partial X \times X \times X$

The claim is that these blow-ups allow the definition of three b-fibrations,

$$\psi_{LM}, \psi_{MR}, \psi_{LR} : (X^3)_\lambda \rightarrow X \times_\lambda X,$$

where the subscripts indicate which factors of X are involved. For example, to get ψ_{LM} we blow down, in order, $\Lambda_M, \Lambda_{MR}, \Lambda_{LR}, S_{MR}, S_{LR}, S_{LMR}, \Lambda_{LMR}$, using Lemma 8.6 to justify the interchange of blow-ups from the original definition of $(X^3)_\lambda$. This leaves us with $[X^3; \Lambda_{LM}; S_{LM}; \Lambda_L; \Lambda_R]$ which equals $(X \times_\lambda X) \times X$, and so the definition of ψ_{LM} is completed with a projection. To check that these maps are b-fibrations is a simple exercise.

In order to apply the pull-back and push-forward formulas, we need to examine the lifts of boundary defining functions from $X \times_\lambda X$ to $(X^3)_\lambda$. Let ρ_l, ρ_r, ρ_f be defining functions of the regular front, right, and crossover faces of $X \times_\lambda X$, and s_l, s_r, s_f defining functions for the crossover faces. On $(X^3)_\lambda$ we will denote defining functions of the regular faces by r and of crossover faces by γ , with subscripts to indicate particular faces. For example, r_L will be the defining function for L , r_{LM} for S_{LM} , r_{LMR} for S_{LMR} , etc. And similarly γ_L for Λ_L , γ_{LM} for Λ_{LM} , etc. By tracing the definitions of the ψ 's backwards, we can compute the lifts of the defining functions from $X \times_\lambda X$ to $(X^3)_\lambda$. The regular and crossover defining functions behave separately and completely analogously to each other, so we can record the lifts in a single chart:

$$(8.9) \quad \begin{array}{ccccccc} & L & M & R & LM & MR & LR & LMR \\ \psi_{LM}^* & 1 & r & - & f & r & 1 & f \\ \psi_{MR}^* & - & 1 & r & 1 & f & r & f \\ \psi_{LR}^* & 1 & - & r & 1 & r & f & f \end{array}$$

This means, for example, that $\psi_{LM}^*(\rho_l) = r_L r_{LR}$ and also $\psi_{LM}^*(s_l) = \gamma_L \gamma_{LR}$, up to smooth non-vanishing functions which we will be dropping throughout this discussion.

Let ν_0 be a smooth non-vanishing section of $\Omega_0^{1/2}(X \times_\lambda X)$. Then for operators represented as kernels $A\nu_0$ and $B\nu_0$ the formula for composition is:

$$(8.10) \quad (A \circ B)\nu_0 = \psi_{LR*} \left[\psi_{LM}^*(A\nu_0) \psi_{MR}^*(B\nu_0) \right].$$

In order to apply the push-forward theorem we need to relate everything to the b-density bundle Ω_b . Let ω_b and ω_{b3} be sections of $\Omega_b(X \times_\lambda X)$ and $\Omega_b((X^3)_\lambda)$ respectively.

Lemma 8.11. *Written as a push-forward of b-densities, the composition formula (8.10) becomes*

$$(8.11) \quad (A \circ B)\omega_b = \psi_{LR*} \left[\psi_{LM}^*(A)\psi_{MR}^*(B)r_M^{-n}\gamma_M^{-n+1}\omega_{b3} \right]$$

Proof. For convenience let us use subscripts to denote lifts by the ψ 's, e.g. $A_{LM} = \psi_{LM}^*A$. Multiplying (8.10) on each side by ν_0 gives

$$(8.12) \quad (A \circ B)\nu_0^2 = \psi_{LR*} \left[A_{LM}B_{MR}(\nu_0)_{LM}(\nu_0)_{MR}(\nu_0)_{LR} \right]$$

If μ is a smooth half-density on $X \times X$, then

$$(8.13) \quad \mu_{LM}\mu_{MR}\mu_{LR} = \mu_3^2,$$

where μ_3 is a smooth half-density on $(X^3)_\lambda$. Let $\beta : X \times_\lambda X \rightarrow X \times X$ be the blow-down. By computing the codimensions of the submanifolds to be blown-up, we can see that

$$\beta^*\Omega^{1/2}(X \times X) = \rho_f^{\frac{n+1}{2}}(s_l s_r)^{\frac{1}{2}} s_f^{\frac{n+2}{2}} \Omega^{1/2}(X \times_\lambda X),$$

so that

$$(8.14) \quad \nu_0 = (\rho_l \rho_r)^{-\frac{n+1}{2}} \rho_f^{-(n+1)} (s_l s_r)^{-\frac{n+1}{2}} s_f^{-(n+1)} \beta^* \mu.$$

Let β_3 be the blow down $(X^3)_\lambda \rightarrow X^3$ and ω a smooth density on $(X^3)_\lambda$. Again, by computing codimensions we can see that

$$(8.15) \quad \beta_3^* \mu_3^2 = (r_{LM} r_{MR} r_{LR})^{n+1} r_{LMR}^{2n+2} (\gamma_L \gamma_M \gamma_R) (\gamma_{LM} \gamma_{MR} \gamma_{LR})^{n+2} \gamma_{LMR}^{2n+4} \omega.$$

Using the liftings (8.9) and combining the properties (8.13), (8.14), and (8.15) we then obtain

$$(\nu_0)_{LM}(\nu_0)_{MR}(\nu_0)_{LR} = r^{-(n+1)}\gamma^{-n}\omega,$$

where r is the product of all defining functions of the regular faces and γ the same for the crossover faces. The composition formula (8.12) then becomes

$$(A \circ B)\rho^{-n}s^{-n+1}\omega_b = \psi_{LR*}\left[A_{LM}B_{MR}r^{-n}\gamma^{-n+1}\omega_{b3}\right],$$

where $\rho = \rho_l\rho_r\rho_f$ and $s = s_ls_rs_f$. The result follows because

$$\frac{r\gamma}{\psi_{LR}^*(\rho s)} = r_M\gamma_M.$$

□

Now let us prove the composition results needed to handle the Neumann series for $(I - F)^{-1}$. Let F' be an asymptotic summation of the series $\sum_{l=1}^{\infty} F^l$ at the front crossover face. Then $(\hat{\Delta} - \lambda)W(I + F')$ will vanish to infinite order at both front faces. The first step is to analyze F^l , for which we need the following:

Lemma 8.12. *Let $\mathcal{F} = (\infty, \sigma_r, \infty, [\frac{n+1}{2}]_+, [\frac{n}{2}], [\frac{1}{2}]_+)$. Then $\mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2})$ is closed under composition.*

Proof. With $A\nu_0, B\nu_0 \in \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2})$, we will compute $(A \circ B)$ from the formula (8.11). A_{LM} and B_{MR} are most succinctly described with a chart of index sets akin to (8.9). Fortunately we can consider the regular and crossover faces separately. At the regular faces we have:

$$(8.16) \quad \begin{array}{ccccc} & \text{L} & \text{M} & \text{R} & \text{LM} & \text{MR} & \text{LR} & \text{LMR} \\ A_{LM} & \infty & \sigma_M & - & \infty & \sigma_R & \infty & \infty \\ B_{MR} & - & \infty & \sigma_R & \infty & \infty & \sigma_R & \infty \end{array}$$

and at the crossover faces:

$$(8.17) \quad \begin{array}{ccccc} & \text{L} & \text{M} & \text{R} & \text{LM} & \text{MR} & \text{LR} & \text{LMR} \\ A_{LM} & [\frac{n+1}{2}]_+ & [\frac{n}{2}] & - & [\frac{1}{2}]_+ & [\frac{n}{2}] & [\frac{n+1}{2}]_+ & [\frac{1}{2}]_+ \\ B_{MR} & - & [\frac{n+1}{2}]_+ & [\frac{n}{2}] & [\frac{n+1}{2}]_+ & [\frac{1}{2}]_+ & [\frac{n}{2}] & [\frac{1}{2}]_+ \end{array}$$

Under ψ_{LR} the faces which map to the interior are \tilde{M} and $\tilde{\Lambda}_M$. From (8.17) we see that the combination $A_{LM}B_{MR}$ vanishes to infinite order at \tilde{M} , while at $\tilde{\Lambda}_M$ the index set is $[n + \frac{1}{2}]_+$, so the push-forward is well-defined.

Notice that $A_{LM}B_{MR}$ vanishes to infinite order at all of the regular faces of $(X^3)_{\lambda}$ except \tilde{R} , where it is polyhomogeneous conormal with index σ_R . Thus $\rho_r^{-\tilde{\sigma}_r}(A \circ B)\omega_b$ will be the pushforward of a b-density with index set $\{(k, k); k \in \mathbb{N}_0\}$ at \tilde{R} and ∞ at all the other regular faces. By Proposition 8.10 we conclude that $(A \circ B)$ has orders ∞, σ_r, ∞ at the left, right, and front regular faces.

As for the crossover faces, by (8.17) and Proposition 8.10 the index sets of $(A \circ B)$ are $[\frac{n+1}{2}]_+ \cup [\frac{n}{2} + 1]_+$ at the left crossover, $[\frac{n}{2}] \cup [\frac{n+1}{2}]_+$ at the right crossover, and $[1]_+ \cup [n + \frac{1}{2}]_+$ at the front crossover face. It is a trivial observation that for $a < b$

$$[a] \cup [b]_+ = [a], \quad [a]_+ \cup [b]_+ = [a]_+,$$

and the result follows. □

Applying this Lemma to the powers of F , we may conclude that

$$F' \in \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}); \quad \mathcal{F} = (\infty, \sigma_r, \infty, [\frac{n+1}{2}]_+, [\frac{n}{2}], [\frac{1}{2}]_+).$$

Actually, this doesn't quite follow directly from Lemma 8.12. We need to know in addition that at each order there is a bound on the highest logarithmic power in F^l at the front crossover face

which is uniform for $l \in \mathbb{N}_0$. This can be deduced from the fact that the index set of F^l at the front crossover face is really $[\frac{l}{2}]_+$, as one can see from the proof of Lemma 8.12.

The improved parametrix is $M = W(I + F')$, which by the construction of F' satisfies

$$(8.18) \quad I - (\hat{\Delta} - \lambda)M = E \in \mathcal{A}_{\mathcal{E}}(X \times_{\lambda} X; \Omega_0^{1/2}),$$

where $\mathcal{E} = (\infty, \sigma_r, \infty, [\frac{n+1}{2}]_+, [\frac{n}{2}], \infty)$.

Proposition 8.13. *For \mathcal{M}, \mathcal{F} as above we have*

$$(8.19) \quad \begin{aligned} {}^0\Psi^*(X; \Omega_0^{1/2}) \circ \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}) &\subset \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}) \\ \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2}) \circ \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}) &\subset \mathcal{A}_{\mathcal{M} \circ \mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}), \end{aligned}$$

where $(\mathcal{M} \circ \mathcal{F}) = (\sigma_l, \sigma_r, 2\sigma_f, [\frac{n}{2}], [\frac{n}{2}], [\frac{1}{2}]_+)$.

Proof. Let us start with the second formula in (8.19). Suppose that

$$A\nu_0 \in \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2}), \quad B\nu_0 \in \mathcal{A}_{\mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2}).$$

As in the proof of Lemma 8.12, we examine the behavior of the lifts to $(X^3)_{\lambda}$. At the regular faces we have:

$$(8.20) \quad \begin{array}{cccccccc} & \text{L} & \text{M} & \text{R} & \text{LM} & \text{MR} & \text{LR} & \text{LMR} \\ A_{LM} & \sigma_L & \sigma_M & - & 0 & \sigma_R & \sigma_R & 0 \\ B_{MR} & - & \infty & \sigma_R & \infty & \infty & \sigma_R & \infty \end{array}$$

In order to apply Proposition 8.10 we consider $x^{-\tilde{\sigma}_l} x'^{-\tilde{\sigma}_r} (A \circ B)$, which is the push-forward of a b-density on $(X^3)_{\lambda}$ with index set $\{(k, k); k \in \mathbb{N}_0\}$ at \tilde{L} , \tilde{R} , and \tilde{S}_{LR} , and ∞ otherwise. Then pushforward gives indices $(\sigma_l, \sigma_r, 2\sigma_f)$ for $A \circ B$ at the regular faces.

The index chart for the crossover faces:

$$(8.21) \quad \begin{array}{cccccccc} & \text{L} & \text{M} & \text{R} & \text{LM} & \text{MR} & \text{LR} & \text{LMR} \\ A_{LM} & [\frac{n}{2}] & [\frac{n}{2}] & - & 0 & [\frac{n}{2}] & [\frac{n}{2}] & 0 \\ B_{MR} & - & [\frac{n+1}{2}]_+ & [\frac{n}{2}] & [\frac{n+1}{2}]_+ & [\frac{1}{2}]_+ & [\frac{n}{2}] & [\frac{1}{2}]_+ \end{array}$$

We conclude that the crossover index sets for $A \circ B$ are $([\frac{n}{2}], [\frac{n}{2}], [\frac{1}{2}]_+)$.

The first formula in (8.19) is proven in exactly the same way. If B is as above, but $A\nu_0 \in {}^0\Psi^*(X; \Omega_0^{1/2})$, then the product $A_{LM}B_{MR}$ will have an interior singularity at the lift of the diagonal through ψ_{LM} . One can check that ψ_{LR*} annihilates this singularity by standard wave-front set arguments (see [2] for an explicit discussion of this). Then the proof of push-forward to $\mathcal{A}_{\mathcal{M}}$ is exactly as above. \square

Corollary 8.14. *The operator $M = W(I + F')$ satisfies*

$$M \in {}^0\Psi^{-2}(X; \Omega_0^{1/2}) + \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2}).$$

Proof. Let $W = W_1 + W_2$ as an element of ${}^0\Psi^{-2}(X; \Omega_0^{1/2}) + \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2})$. From (8.19) we immediately see that

$$\begin{aligned} W_2 + W_1 F' &\in \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2}), \\ W_2 F' &\in \mathcal{A}_{(\mathcal{M} \circ \mathcal{F})}(X \times_{\lambda} X; \Omega_0^{1/2}). \end{aligned}$$

Now consider the equation (8.18). By construction $I - (\hat{\Delta} - \lambda)W_1 = Q$, which is smooth up to the front face, and since Δ lifts to $\text{Diff}_b^*(X \times_{\lambda} X)$ we conclude that

$$(\hat{\Delta} - \lambda)(W_2 F') \in \mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2}).$$

This means that $\hat{\Delta} - \lambda$ must annihilate all of the terms in the asymptotic expansion of $(W_2 F')$ at the front regular face, since an expansion containing $\rho_f^{2\sigma_f}$ is not allowed in $\mathcal{A}_{\mathcal{M}}$. We can argue term by term using the normal operator to show that these coefficients are zero. For example, at leading order we have

$$(8.22) \quad N_q(\hat{\Delta} - \lambda)N_q(x'^{-2\sigma_f} W_2 F') = 0,$$

for all $q \in \partial X \setminus \Lambda$. From the definition of $\mathcal{A}_{\mathcal{M} \circ \mathcal{F}}(X \times_{\lambda} X; \Omega_0^{1/2})$ we see that

$$N_q(x'^{-2\sigma_f} W_2 F') \in \mathcal{A}_{\sigma(q), \sigma(q)}(F_q; \Omega_0^{1/2}).$$

Applying Proposition 6.4 (in the model case with constant indicial root) to (8.22), we conclude that $N_q(x'^{-2\sigma_f} W_2 F') = 0$. Using this argument inductively, we conclude that $W_2 F'$ vanishes to infinite order at the front face, which puts it in $\mathcal{A}_{\mathcal{M}}(X \times_{\lambda} X; \Omega_0^{1/2})$. \square

Next we show that the structure of the error term E allows it to be realized as a conormal function on $X_{\lambda} \times X_{\lambda}$ rather than $X \times_{\lambda} X$. Because we can realize $X \times_{\lambda} X$ as $[X \times X; \Lambda_l; \Lambda_r; \Lambda_f; S]$, by various applications of Lemma 8.6, there is a well-defined blow-down $\phi : X \times_{\lambda} X \rightarrow X_{\lambda} \times X_{\lambda}$. This is a b-map, but not a b-fibration ($\tilde{\Lambda}_f$ is mapped into a corner, for example).

Lemma 8.15. *Suppose as above that*

$$E \in \mathcal{A}_{\mathcal{E}}(X \times_{\lambda} X; \Omega_0^{1/2}), \quad \mathcal{E} = (\infty, \sigma_r, \infty, [\frac{n+1}{2}]_+, [\frac{n}{2}], \infty).$$

Then if we lift E from the interior $(X \times X)^{\circ}$ to $X_{\lambda} \times X_{\lambda}$ we have

$$E \in \mathcal{A}_{\mathcal{H}}(X_{\lambda} \times X_{\lambda}; \Omega_0^{1/2}), \quad \mathcal{H} = (\infty, \sigma_r, [\frac{n+1}{2}]_+, [\frac{n}{2}])$$

Proof. First note that $\mathcal{V}_b(X_{\lambda} \times X_{\lambda})$ lifts under ϕ to $(\rho_f s_f)^{-1} \mathcal{V}_b(X \times_{\lambda} X)$, as may be easily checked in local coordinates. Observe that

$$x^{-\frac{n+1}{2}} x'^{-\tilde{\sigma}_r} E \in \mathcal{A}^{(\infty, 0, \infty, 0, 0, \infty)^-}(X \times_{\lambda} X).$$

Because of the infinite order of vanishing at the two front faces, we deduce that

$$x^{-\frac{n+1}{2}} x'^{-\tilde{\sigma}_r} E \in \mathcal{A}^{(\infty, 0, 0, 0)^-}(X_{\lambda} \times X_{\lambda})$$

Let V_l, V_r, W_l, W_r be radial vector fields at the left/right regular and left/right crossover boundary faces of $X_{\lambda} \times X_{\lambda}$, respectively. We claim the lift by ϕ of V_l is a radial vector field \tilde{V}_l at the left regular face, possibly plus a term in $\rho_l s_f^{-1} \mathcal{V}_b(X \times_{\lambda} X)$. Similarly, W_l lifts to a radial vector field \tilde{W}_l at the left crossover face, possibly plus a term in $s_l \rho_f^{-1} \mathcal{V}_b(X \times_{\lambda} X)$. The behavior on the right is analogous. These facts are best checked in local coordinates. On $X_{\lambda} \times X_{\lambda}$ we can use coordinates $(u, \theta, \bar{y}, u', \theta', \bar{y}')$, such that $x = u \cos \theta$, $y_n = u \sin \theta$, $y = (\bar{y}, y_n)$, and similarly on the right. For V_l and W_l we can take $(\cos \theta) \partial_{\theta}$ and $u \partial_u$.

Near $\tilde{\Lambda}_l$ and $\tilde{\Lambda}_r$ we ignore the blow-up of S , since \tilde{S} does not intersect these. So we can use the coordinates $(R, \eta, \eta', \omega, \theta, \theta', \bar{y})$, where $R = \sqrt{r^2 + r'^2 + (\bar{y} - \bar{y}')^2}$ and $(\eta, \eta', \omega) = (r, r', \bar{y} - \bar{y}')/R$. Then $\tilde{W}_l = (\cos \theta) \partial_{\theta}$ again, which is indeed a radial vector field at the left regular face $\{\cos \theta = 0\}$. The lift of V_l is

$$\tilde{V}_l = \eta \partial_{\eta} + \eta^2 [R \partial_R - \eta \partial_{\eta} - \eta' \partial_{\eta'} - \omega \partial_{\omega}],$$

which is a radial vector field at the left crossover face $\{\eta = 0\}$. Similarly, with a different coordinate system we could check this in a neighborhood of S (then we could ignore the blow-ups of Λ_l and Λ_r).

Of course, the radial vector fields are not uniquely defined. Another choice of V_l would differ by a field in $t_l \mathcal{V}_b(X_{\lambda} \times X_{\lambda})$, where t_l is a defining function for the left regular face of $X_{\lambda} \times X_{\lambda}$. Since

$\phi^* t_l = \rho_l \rho_f$, $t_l \mathcal{V}_b(X_\lambda \times X_\lambda)$ lifts to $\rho_l s_f^{-1} \mathcal{V}_b(X \times_\lambda X)$, which agrees with the correction term given above.

Now we can show $E \in \mathcal{A}_\mathcal{H}(X_\lambda \times X_\lambda; \Omega_0^{1/2})$ by pulling these radial vector fields up to $X \times_\lambda X$. (Once again the infinite order of vanishing at the front faces is crucial.) For example, $E \in \mathcal{A}_\mathcal{E}(X \times_\lambda X; \Omega_0^{1/2})$ entails the estimate

$$\tilde{V}_r(x^{-\frac{n+1}{2}} x'^{-\tilde{\sigma}_r} E) \in \mathcal{A}^{(\infty, 1, \infty, 0, 0, \infty)-}(X \times_\lambda X),$$

and this would be unaffected if we add to \tilde{V}_r a term in $\rho_r s_f^{-1} \mathcal{V}_b(X \times_\lambda X)$. Consequently, it implies the estimate

$$V_r(x^{-\frac{n+1}{2}} x'^{-\tilde{\sigma}_r} E) \in \mathcal{A}^{(\infty, 1, 0, 0)-}(X_\lambda \times X_\lambda).$$

In a similar way all of the estimates needed to show $E \in \mathcal{A}_\mathcal{H}(X_\lambda \times X_\lambda; \Omega_0^{1/2})$ can be deduced. \square

We consider next the composition of a kernel living on $X \times_\lambda X$ with a kernel on $X_\lambda \times X_\lambda$. For this purpose we can use the slightly simpler space

$$(X \times_\lambda X) \times X_\lambda = [X^3; \Lambda_{LM}; S_{LM}; S_{LR}; \Lambda_L; \Lambda_M; \Lambda_R]$$

instead of $(X^3)_\lambda$ for the triple product. We'll continue to denote the projections onto pairs by $\psi_{LM}, \psi_{MR}, \psi_{LR}$, where ψ_{LM} projects to $X \times_\lambda X$ and ψ_{MR} and ψ_{LR} are blow-downs to $(X_\lambda)^3$ followed by projection onto $X_\lambda \times X_\lambda$. The chart (8.9) of lifts of defining functions is abbreviated to

$$(8.23) \quad \begin{array}{ccccc} & \text{L} & \text{M} & \text{R} & \text{LM} \\ \psi_{LM}^* & 1 & r & - & f \\ \psi_{MR}^* & - & 1 & r & 1 \\ \psi_{LR}^* & 1 & - & r & 1 \end{array}$$

Let ν_0 be a section of $\Omega_0^{1/2}(X \times_\lambda X)$ and μ_0 a section of $\Omega_0^{1/2}(X_\lambda \times X_\lambda)$. The push-forward formula for composition of $A\nu_0$ with $B\mu_0$ is

$$(A \circ B)\mu_0 = \psi_{LR*} \left[A_{LM} B_{MR} (\nu_0)_{LM} (\mu_0)_{MR} \right].$$

Computing as in the proof of Lemma 8.10, we derive

$$(8.24) \quad (A \circ B)\omega_b = \psi_{LR*} \left[A_{LM} B_{MR} \rho_M^{-n} \gamma_M^{-n+1} \omega_{b3} \right],$$

Lemma 8.16. *With*

$$\mathcal{M} = (\sigma_l, \sigma_r, 0, [\frac{n}{2}], [\frac{n}{2}], [0]), \quad \mathcal{H} = (\infty, \sigma_r, [\frac{n+1}{2}]_+, [\frac{n}{2}]),$$

as above, we have the compositions

$$\begin{aligned} \mathcal{A}_\mathcal{M}(X \times_\lambda X; \Omega_0^{1/2}) \circ \mathcal{A}_\mathcal{H}(X_\lambda \times X_\lambda; \Omega_0^{1/2}) &\subset \mathcal{A}_\mathcal{I}(X_\lambda \times X_\lambda; \Omega_0^{1/2}) \\ {}^0\Psi^{-2}(X; \Omega_0^{1/2}) \circ \mathcal{A}_\mathcal{H}(X_\lambda \times X_\lambda; \Omega_0^{1/2}) &\subset \mathcal{A}_\mathcal{H}(X_\lambda \times X_\lambda; \Omega_0^{1/2}) \end{aligned}$$

where $\mathcal{I} = (\sigma_l, \sigma_r, [\frac{n}{2}], [\frac{n}{2}])$.

Proof. Let $A\nu_0 \in \mathcal{A}_\mathcal{M}(X \times_\lambda X; \Omega_0^{1/2})$ and $B\mu_0 \in \mathcal{A}_\mathcal{H}(X_\lambda \times X_\lambda; \Omega_0^{1/2})$. As in the proof of Lemma 8.12, we use a chart to describe the boundary behavior of $A_{LM} B_{MR}$. For the regular faces we have:

$$\begin{array}{ccccc} & \text{L} & \text{M} & \text{R} & \text{LM} \\ \psi_{LM}^* & \sigma_L & \sigma_M & - & \sigma_{LM} \\ \psi_{MR}^* & - & \infty & \sigma_R & \infty \end{array}$$

and at the crossover faces:

$$\begin{array}{ccccc} & L & M & R & LM \\ \psi_{LM}^* & [\frac{n}{2}] & [\frac{n}{2}] & - & [\frac{n}{2}] \\ \psi_{MR}^* & - & [\frac{n+1}{2}]_+ & [\frac{n}{2}] & [\frac{n+1}{2}]_+ \end{array}$$

The behavior at the middle faces, together with (8.24), shows that the push-forward is well defined. And the form of \mathcal{I} is deduced from (8.23) and Proposition 8.10.

The second formula is handled in the same way. As in Proposition 8.13 the push-forward annihilates the interior singularity. \square

As a final topic of this subsection, we establish a mapping property that will be used in the characterization of generalized eigenfunctions.

Lemma 8.17. *With,*

$$\mathcal{M} = (\sigma_l, \sigma_r, 0, [\frac{n}{2}], [\frac{n}{2}], [0]), \quad \mathcal{I} = (\sigma_l, \sigma_r, [\frac{n}{2}], [\frac{n}{2}]),$$

we have the mapping properties:

$$\begin{aligned} {}^0\Psi^*(X; \Omega_0^{1/2}) \circ \mathcal{A}_{\infty, [\frac{n+1}{2}]_+}(X_\lambda) &\subset \mathcal{A}_{\infty, [\frac{n+1}{2}]_+}(X_\lambda) \\ \mathcal{A}_{\mathcal{M}}(X \times_\lambda X; \Omega_0^{1/2}) \circ \mathcal{A}_{\infty, [\frac{n+1}{2}]_+}(X_\lambda) &\subset \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda) \\ \mathcal{A}_{\mathcal{I}}(X_\lambda \times X_\lambda; \Omega_0^{1/2}) \circ \mathcal{A}_{\infty, [\frac{n+1}{2}]_+}(X_\lambda) &\subset \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda) \end{aligned}$$

Proof. We will prove only the second of the three formulas. The first follows by similar argument because of the cancelation of the interior singularity as in Proposition 8.13. The third formula follows by an analogous but even simpler argument on $X_\lambda \times X_\lambda$.

Let $(A\nu_0) \in \mathcal{A}_{\mathcal{M}}(X \times_\lambda X; \Omega_0^{1/2})$, where ν_0 is a section of $\Omega_0^{1/2}(X \times_\lambda X)$. As noted in the remarks following (8.6), there are b-fibrations

$$\beta_L, \beta_R : X \times_\lambda X \rightarrow X_\lambda$$

projecting through the left and right factors. The action of the operator with kernel $A\nu_0$ on $u\gamma_0 \in \mathcal{A}_{\infty, [\frac{n+1}{2}]_+}(X_\lambda)$, where $\gamma_0 \in C^\infty(X_\lambda; \Omega_0^{1/2})$, is given by

$$(A \circ u)\gamma_0 = \beta_{L*} [A\nu_0 \cdot \beta_R^*(u\gamma_0)]$$

Multiplying both sides by γ_0 , we can recast this in a form suitable for push-forward:

$$(A \circ u)\mu_b = \beta_{L*} [Au_R \cdot \rho_r^{-n} s_r^{-n+1} \omega_b],$$

where u_R is shorthand for $\beta_R^* u$, $\omega_b \in C^\infty(X \times_\lambda X, \Omega_b)$, and $\mu_b \in C^\infty(X_\lambda; \Omega_b)$. The combination Au_R has index family $(\sigma_l, \infty, \infty, [\frac{n}{2}], [\frac{n+1}{2}]_+, [\frac{n+1}{2}]_+)$, so the push-forward is well-defined. Multiplying $(A \circ u)$ by $x^{-\tilde{\sigma}}$ and applying the push-forward result Proposition 8.10 tells us that $x^{-\tilde{\sigma}}(A \circ u)$ has index family $(0, [0] \sqcup [\frac{1}{2}]_+)$, and the result follows. \square

8.5. Resolvent kernel. Consider the operator $\Delta - \lambda$ restricted to a domain defined by the radiation condition:

$$\mathcal{D}_\lambda = \{u \in x^{-\delta} L^2(X; \Omega_0^{1/2}) : (x\partial_x - \sigma)u \in x^\delta L^2(X; \Omega_0^{1/2})\} \cap H^2(X; \Omega_0^{1/2}),$$

for some small $\delta > 0$. Thus

$$\hat{\Delta} - \lambda : \mathcal{D}_\lambda \rightarrow x^\delta L^2(X; \Omega_0^{1/2}).$$

The limiting absorption principle shows the existence of an inverse

$$R_\zeta : x^\delta L^2(X; \Omega_0^{1/2}) \rightarrow \mathcal{D}_\lambda,$$

but we do not know the structure of its kernel.

On the other hand, in §8.4 we obtained the parametrix M such that

$$(\hat{\Delta} - \lambda)M = 1 - E \text{ on } x^\delta L^2(X; \Omega_0^{1/2}),$$

where we do know the structure of M and E . For $u \in \mathcal{D}_\lambda$, integration by parts is justified so that we can take the transpose

$$M^t(\hat{\Delta} - \lambda) = 1 - E^t,$$

as a relation on \mathcal{D}_λ . With these relations we can write

$$\begin{aligned} M &= R_\zeta(\Delta - \lambda)M = R_\zeta - R_\zeta E \\ M^t &= M^t(\Delta - \lambda)R_\zeta = R_\zeta - E^t R_\zeta \end{aligned}$$

And so we can deduce

$$(8.25) \quad R_\zeta = M + R_\zeta E = M + M^t E + E^t R_\zeta E.$$

By Corollary 8.14

$$M^t \in {}^0\Psi^{-2}(X; \Omega_0^{1/2}) + \mathcal{A}_\mathcal{M}(X \times_\lambda X; \Omega_0^{1/2}).$$

(Taking the transpose of an index family interchanges left and right index sets, but \mathcal{M} is symmetric.) Then by Lemma 8.16 we have

$$(8.26) \quad M^t E \in \mathcal{A}_\mathcal{I}(X_\lambda \times X_\lambda; \Omega_0^{1/2})(X; \Omega_0^{1/2}), \quad \mathcal{I} = (\sigma_l, \sigma_r, [\frac{n}{2}], [\frac{n}{2}]).$$

To deal with $E^t R_\zeta E$, we can at least use the fact that R_ζ is bounded as a map $x^\delta L^2 \rightarrow x^{-\delta} L^2$ for small $\delta > 0$.

Lemma 8.18.

$$\begin{aligned} \mathcal{A}_{\mathcal{H}^t}(X_\lambda \times X_\lambda; \Omega_0^{1/2}) \circ \mathcal{L}(x^\delta L^2, x^{-\delta} L^2) \circ \mathcal{A}_\mathcal{H}(X_\lambda \times X_\lambda; \Omega_0^{1/2}) \\ \subset \mathcal{A}_\mathcal{I}(X_\lambda \times X_\lambda; \Omega_0^{1/2})(X; \Omega_0^{1/2}), \end{aligned}$$

where $\mathcal{I} = (\sigma_l, \sigma_r, [\frac{n}{2}], [\frac{n}{2}])$.

Proof. Since the index family \mathcal{H} implies $x^\delta L^2$ decay at the left face, the composition is represented by a convergent integral. The necessary estimates can be obtained by differentiating under the integral using dominated convergence. \square

With (8.26) and Lemma 8.18 we deduce immediately from (8.25) the main result of this section:

Theorem 8.19. *For ζ such that $\lambda = \alpha_0^2 \zeta(n - \zeta) \in (\frac{\alpha_0^2 n^2}{4}, \frac{\alpha_1^2 n^2}{4})$ and satisfying the generic assumption (8.1), the kernel of the resolvent $R_\zeta = [\hat{\Delta} - \lambda]^{-1}$ defined by the limiting absorption principle has the structure*

$$R_\zeta \in {}^0\Psi^{-2}(X; \Omega_0^{1/2}) + \mathcal{A}_\mathcal{M}(X \times_\lambda X; \Omega_0^{1/2}) + \mathcal{A}_\mathcal{I}(X_\lambda \times X_\lambda; \Omega_0^{1/2}),$$

with $\mathcal{M} = (\sigma_l, \sigma_r, 0, [\frac{n}{2}], [\frac{n}{2}], 0)$ and $\mathcal{I} = (\sigma_l, \sigma_r, [\frac{n}{2}], [\frac{n}{2}])$.

With this knowledge of the structure of the resolvent kernel, we can give a more refined version of Proposition 7.1, describing the generalized eigenfunctions.

Proposition 8.20. *For ζ, λ as in Theorem 8.19, given $f \in C^\infty(\partial X)$ we can solve $(\Delta - \lambda)u = 0$ for*

$$u \in \mathcal{A}_{n-\sigma, [\frac{n}{2}]}(X_\lambda) + \mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda),$$

such that

$$u \sim x^{n-\sigma} f + x^\sigma f' \text{ near } W_\lambda,$$

with $f' \in \mathcal{A}_{[\frac{n}{2}]}(\overline{W_\lambda})$. This u is uniquely determined by $f|_{\overline{W_\lambda}}$

Proof. Using Proposition 8.4 we solve for $u_1 \in \mathcal{A}_{n-\sigma, [\frac{n}{2}]}(X_\lambda)$ and asymptotic to $x^{n-\sigma}f$ near W_λ , such that $(\Delta - \lambda)u_1 = \phi \in \mathcal{A}_{\infty, [\frac{n+1}{2}]_+}(X_\lambda)$. Then let $u_2 = -R_\zeta \phi$, which is in $\mathcal{A}_{\sigma, [\frac{n}{2}]}(X_\lambda)$ by Lemma 8.17. Thus $u = u_1 + u_2$ has the stated properties. \square

In particular, under these assumptions the scattering matrix defined in Theorem 7.2 extends to a map

$$S_\lambda : C^\infty(\overline{W_\lambda}) \rightarrow \mathcal{A}_{[\frac{n}{2}]}(\overline{W_\lambda}).$$
